

**NAME**

curl-config – Get information about a libcurl installation

**SYNOPSIS**

**curl-config** [options]

**DESCRIPTION**

**curl-config** displays information about a previous curl and libcurl installation.

**OPTIONS**

- ca** Displays the built-in path to the CA cert bundle this libcurl uses.
- cc** Displays the compiler used to build libcurl.
- cflags** Set of compiler options (CFLAGS) to use when compiling files that use libcurl. Currently that is only the include path to the curl include files.
- feature**  
Lists what particular main features the installed libcurl was built with. At the time of writing, this list may include SSL, KRB4 or IPv6. Do not assume any particular order. The keywords will be separated by newlines. There may be none, one or several keywords in the list.
- help** Displays the available options.
- libs** Shows the complete set of libs and other linker options you will need in order to link your application with libcurl.
- prefix** This is the prefix used when libcurl was installed. Libcurl is then installed in \$prefix/lib and its header files are installed in \$prefix/include and so on. The prefix is set with "configure --prefix".
- version**  
Outputs version information about the installed libcurl.
- vernum**  
Outputs version information about the installed libcurl, in numerical mode. This outputs the version number, in hexadecimal, with 8 bits for each part; major, minor, patch. So that libcurl 7.7.4 would appear as 070704 and libcurl 12.13.14 would appear as 0c0d0e...

**EXAMPLES**

What linker options do I need when I link with libcurl?

```
$ curl-config --libs
```

What compiler options do I need when I compile using libcurl functions?

```
$ curl-config --cflags
```

How do I know if libcurl was built with SSL support?

```
$ curl-config --feature | grep SSL
```

What's the installed libcurl version?

```
$ curl-config --version
```

How do I build a single file with a one-line command?

```
$ 'curl-config --cc --cflags --libs' -o example example.c
```
