## Contents

<b>01</b>	<b>ltdirchk.dtx</b>	<b>1</b>
<b>1</b>	<b>L<sup>A</sup>T<sub>E</sub>X System Dependent Initializations</b>	<b>1</b>
<b>2</b>	<b>Initialization</b>	<b>2</b>
2.1	INITEX . . . . .	3
2.2	Some bits of 2e . . . . .	4
<b>3</b>	<b>texsys.cfg</b>	<b>5</b>
3.1	texsys.cfg . . . . .	5
3.2	UNIX (web2c) . . . . .	6
3.3	UNIX (other) . . . . .	7
3.4	MSDOS (emtex) . . . . .	7
3.5	MSDOS (other) . . . . .	7
3.6	VMS (DECUS T <sub>E</sub> X, PD VMS 3.6) . . . . .	7
3.7	VMS (???) . . . . .	7
3.8	MACINTOSH (OzTeX 1.6) . . . . .	8
3.9	MACINTOSH (other) . . . . .	8
3.10	FAKE EXAMPLE . . . . .	8
<b>4</b>	<b>Setting \@currdir</b>	<b>9</b>
<b>5</b>	<b>Setting \input@path</b>	<b>10</b>

<b>6</b>	<b>Filename Parsing</b>	<b>11</b>
<b>7</b>	<b>T<sub>E</sub>X Versions</b>	<b>13</b>
<b>8</b>	<b>ltxcheck.tex</b>	<b>13</b>
<b>02</b>	<b>lplain.dtx</b>	<b>14</b>
<b>1</b>	<b>Plain T<sub>E</sub>X</b>	<b>14</b>
<b>03</b>	<b>ltvers.dtx</b>	<b>35</b>
<b>1</b>	<b>Version Identification</b>	<b>35</b>
1.1	Declaring an all-new module . . . . .	38
<b>04</b>	<b>l luatex.dtx</b>	<b>40</b>
<b>1</b>	<b>Overview</b>	<b>40</b>
<b>2</b>	<b>Core T<sub>E</sub>X functionality</b>	<b>40</b>
<b>3</b>	<b>Plain T<sub>E</sub>X interface</b>	<b>41</b>
<b>4</b>	<b>Lua functionality</b>	<b>41</b>
4.1	Allocators in Lua . . . . .	41
4.2	Lua access to T <sub>E</sub> X register numbers . . . . .	42
4.3	Module utilities . . . . .	43
4.4	Callback management . . . . .	43
<b>5</b>	<b>Implementation</b>	<b>44</b>
5.1	Minimum LuaT <sub>E</sub> X version . . . . .	44
5.2	Older L <sup>A</sup> T <sub>E</sub> X/Plain T <sub>E</sub> X setup . . . . .	45
5.2.1	Fixes to <code>etex.src/etex.sty</code> . . . . .	45
5.2.2	luatex specific settings . . . . .	46
5.3	Attributes . . . . .	47
5.4	Category code tables . . . . .	47
5.5	Named Lua functions . . . . .	49
5.6	Custom whatsits . . . . .	49
5.7	Lua bytecode registers . . . . .	50
5.8	Lua chunk registers . . . . .	50
5.9	Lua loader . . . . .	50
5.10	Lua module preliminaries . . . . .	52
5.11	Lua module utilities . . . . .	52
5.11.1	Module tracking . . . . .	52
5.11.2	Module messages . . . . .	53
5.12	Accessing register numbers from Lua . . . . .	54
5.13	Attribute allocation . . . . .	55
5.14	Custom whatsit allocation . . . . .	56

5.15	Bytecode register allocation	56
5.16	Lua chunk name allocation	56
5.17	Lua function allocation	57
5.18	Lua callback management	57
5.18.1	Housekeeping	57
5.18.2	Handlers	62
5.18.3	Public functions for callback management	65
<b>05</b>	<b>ltxpl.dtx</b>	<b>71</b>
<b>1</b>	<b>expl3-dependent code</b>	<b>71</b>
1.1	Loader	71
1.2	Using expl3 code	74
<b>2</b>	<b>Document-level command names for expl3 functions</b>	<b>75</b>
<b>06</b>	<b>ltdfns.dtx</b>	<b>78</b>
<b>1</b>	<b>Definitions</b>	<b>78</b>
1.1	Initex initializations	78
1.2	Saved versions of TeX primitives	78
1.3	Command definitions	79
1.4	Robust commands and protect	89
1.5	Acting on robust commands	96
1.5.1	Copying robust commands	98
1.5.2	Showing robust commands	101
1.5.3	Commands defined with <code>\DeclareRobustCommand</code>	101
1.5.4	Commands defined with <code>\newcommand</code> (with optional argument)	103
1.5.5	Showing environments	105
1.6	Internal defining commands	106
<b>2</b>	<b>Discretionary Hyphenation</b>	<b>110</b>
<b>07</b>	<b>ltxcmd.dtx</b>	<b>113</b>
<b>1</b>	<b>Creating document commands</b>	<b>113</b>
1.1	Variables and constants	113
1.2	Declaring commands and environments	117
1.3	Structure of xparse commands	123
1.4	Normalizing the argument specifications	127
1.5	Preparing the signature: general mechanism	136
1.6	Setting up a standard signature	137
1.7	Setting up expandable types	142
1.7.1	Copying a command and its internal structure	145
1.7.2	Showing the definition of a command	151
1.8	Grabbing arguments	157
1.9	Grabbing arguments expandably	174
1.10	Argument processors	180

1.11	Conversion to key-value form	182
1.12	Utilities	185
1.13	Access to the argument specification	189
1.14	Messages	189
1.15	User functions	195
<b>08</b>	<b>lthooks.dtx</b>	<b>201</b>
<b>1</b>	<b>Introduction</b>	<b>201</b>
<b>2</b>	<b>Package writer interface</b>	<b>201</b>
2.1	L <sup>A</sup> T <sub>E</sub> X 2 <sub>ε</sub> interfaces	201
2.1.1	Declaring hooks	201
2.1.2	Special declarations for generic hooks	202
2.1.3	Using hooks in code	203
2.1.4	Updating code for hooks	204
2.1.5	Hook names and default labels	207
2.1.6	The <code>top-level</code> label	209
2.1.7	Defining relations between hook code	209
2.1.8	Querying hooks	211
2.1.9	Displaying hook code	212
2.1.10	Debugging hook code	213
2.2	L <sup>3</sup> programming layer ( <code>expl3</code> ) interfaces	213
2.3	On the order of hook code execution	216
2.4	The use of “reversed” hooks	218
2.5	Difference between “normal” and “one-time” hooks	219
2.6	Generic hooks provided by packages	219
2.7	Hooks with arguments	220
2.8	Private L <sup>A</sup> T <sub>E</sub> X kernel hooks	222
2.9	Legacy L <sup>A</sup> T <sub>E</sub> X 2 <sub>ε</sub> interfaces	222
<b>3</b>	<b>L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> commands and environments augmented by hooks</b>	<b>223</b>
3.1	Generic hooks	223
3.1.1	Generic hooks for all environments	224
3.1.2	Generic hooks for commands	225
3.1.3	Generic hooks provided by file loading operations	225
3.2	Hooks provided by <code>\begin{document}</code>	226
3.3	Hooks provided by <code>\end{document}</code>	226
3.4	Hooks provided by <code>\shipout</code> operations	228
3.5	Hooks provided for paragraphs	228
3.6	Hooks provided in NFSS commands	228
3.7	Hook provided by the mark mechanism	229

<b>4</b>	<b>The Implementation</b>	<b>229</b>
4.1	Debugging	229
4.2	Borrowing from internals of other kernel modules	230
4.3	Declarations	230
4.4	Providing new hooks	232
4.4.1	The data structures of a hook	232
4.4.2	On the existence of hooks	233
4.4.3	Setting hooks up	234
4.4.4	Disabling and providing hooks	240
4.5	Parsing a label	242
4.6	Adding or removing hook code	246
4.7	Setting rules for hooks code	267
4.8	Specifying code for next invocation	289
4.9	Using the hook	291
4.10	Querying a hook	297
4.11	Messages	301
4.12	L <sup>A</sup> T <sub>Ε</sub> X 2 <sub>ε</sub> package interface commands	304
4.13	Deprecated that needs cleanup at some point	307
4.14	Internal commands needed elsewhere	309
<b>09</b>	<b>ltxcmdhooks.dtx</b>	<b>311</b>
<b>1</b>	<b>Introduction</b>	<b>311</b>
<b>2</b>	<b>Restrictions and Operational details</b>	<b>312</b>
2.1	Patching	313
2.1.1	Timing	313
2.2	Commands that look ahead	313
<b>3</b>	<b>Package Author Interface</b>	<b>314</b>
3.1	Arguments and redefining commands	315
<b>4</b>	<b>The Implementation</b>	<b>315</b>
4.1	Execution plan	315
4.2	Variables	316
4.3	Variants	317
4.4	Patching or delaying	317
4.5	Patching commands	319
4.5.1	Patching by expansion and redefinition	320
4.5.2	Patching by retokenization	328
4.6	Messages	335
<b>10</b>	<b>ltsockets.dtx</b>	<b>337</b>
<b>1</b>	<b>Introduction</b>	<b>337</b>

<b>2</b>	<b>Configuration of the transformation process</b>	<b>337</b>
2.1	The template mechanism . . . . .	337
2.2	The hook mechanism . . . . .	338
2.3	The socket mechanism . . . . .	338
2.3.1	Examples . . . . .	340
2.3.2	Details and semantics . . . . .	341
2.3.3	Command syntax . . . . .	343
2.3.4	Rationale for error handling . . . . .	345
<b>3</b>	<b>The Implementation</b>	<b>345</b>
3.1	Debugging the socket structures . . . . .	345
3.2	The L3 layer commands . . . . .	346
3.3	Error messages . . . . .	350
3.4	The L <sup>A</sup> T <sub>E</sub> X 2 <sub>ε</sub> interface commands . . . . .	350
<b>11</b>	<b>lttemplates.dtx</b>	<b>352</b>
<b>1</b>	<b>Introduction</b>	<b>352</b>
<b>2</b>	<b>What is a document?</b>	<b>352</b>
<b>3</b>	<b>Types, templates, and instances</b>	<b>353</b>
<b>4</b>	<b>Template types</b>	<b>353</b>
<b>5</b>	<b>Templates</b>	<b>353</b>
<b>6</b>	<b>Multiple choices</b>	<b>357</b>
<b>7</b>	<b>Instances</b>	<b>358</b>
<b>8</b>	<b>Document interface</b>	<b>359</b>
<b>9</b>	<b>Changing existing definitions</b>	<b>360</b>
9.1	Expanding the values of keys . . . . .	360
<b>10</b>	<b>Getting information about templates and instances</b>	<b>361</b>
<b>11</b>	<b>The implementation</b>	<b>361</b>
11.1	Variables and constants . . . . .	362
11.2	Testing existence and validity . . . . .	364
11.3	Saving and recovering property lists . . . . .	365
11.4	Creating new template types . . . . .	367
11.5	Design part of template declaration . . . . .	368
11.5.1	Storing values . . . . .	371
11.6	Implementation part of template declaration . . . . .	372
11.7	Editing template defaults . . . . .	377
11.8	Creating instances of templates . . . . .	379
11.9	Using templates directly . . . . .	382
11.10	Assigning values to variables . . . . .	382
11.11	Using instances . . . . .	385

11.12	Assignment manipulation . . . . .	386
11.13	Showing templates and instances . . . . .	386
11.14	Messages . . . . .	387
11.15	User functions . . . . .	391
<b>12</b>	<b>ltdll.dtx</b>	<b>394</b>
<b>1</b>	<b>Counters</b>	<b>394</b>
<b>13</b>	<b>ltdl.dtx</b>	<b>396</b>
<b>1</b>	<b>Program control structure</b>	<b>396</b>
<b>14</b>	<b>ltderr.dtx</b>	<b>400</b>
<b>1</b>	<b>Error handling and tracing</b>	<b>400</b>
1.1	General commands . . . . .	400
1.2	Specific errors . . . . .	406
1.3	Tracing . . . . .	410
<b>15</b>	<b>ltdpar.dtx</b>	<b>411</b>
<b>1</b>	<b>Paragraphs</b>	<b>411</b>
1.1	Implementation . . . . .	411
<b>16</b>	<b>ltdpara.dtx</b>	<b>413</b>
<b>1</b>	<b>Introduction</b>	<b>413</b>
1.1	The default processing done by the engine . . . . .	413
<b>2</b>	<b>The new mechanism implemented for L<sup>A</sup>T<sub>E</sub>X</b>	<b>415</b>
2.1	The provided hooks . . . . .	416
2.2	Altered and newly provided commands . . . . .	417
2.3	Examples . . . . .	418
2.3.1	Testing the mechanism . . . . .	418
2.3.2	Mark the first paragraph of each <code>itemize</code> . . . . .	420
2.4	Some technical notes . . . . .	420
2.4.1	Glue items between paragraphs (found with <code>fancypar</code> ) . . . . .	420
<b>3</b>	<b>The Implementation</b>	<b>421</b>
3.1	Providing hooks for paragraphs . . . . .	421
3.2	The error messages . . . . .	428
<b>17</b>	<b>ltdmeta.dtx</b>	<b>430</b>

<b>1</b>	<b>Introduction</b>	<b>430</b>
1.1	<code>\DocumentMetadata</code> . . . . .	430
<b>2</b>	<b>The Implementation</b>	<b>430</b>
<b>18</b>	<b>ltspace.dtx</b>	<b>433</b>

## File 01

# ltdirchk.dtx

## 1 L<sup>A</sup>T<sub>E</sub>X System Dependent Initializations

This file implements the semi-automatic determination of various system dependent parts of the initialization. The actual definitions may be placed in a file `texsys.cfg`. Thus for operating systems for which the tests here do not result in acceptable settings, a ‘hand written’ `texsys.cfg` may be produced.

The macros that must be defined are:

`\@currdir`      `\@currdir{filename}{space}` should expand to a form of the filename that uniquely refers to the ‘current directory’ if this is possible. (The expansion should also end with a space.) on UNIX, this is `\def\@currdir{./}`. For more exotic operating systems you may want to make `\@currdir` a macro with arguments delimited by `.` and/or `{space}`. If the operating system has no concept of directory structure, this macro should be defined to be empty.

`\input@path`    If the primitive `\openin` searches the same directories as the primitive `\input`, then it is possible to tell (using `\ifeof`) whether a file exists before trying to input it. For systems like this, `\input@path` should be left undefined.

If `\openin` does not ‘follow’ `\input` then `\input@path` must be defined to be a list of directories to search for input files. The format for each directory is as for `\@currdir`, normally just a prefix is required, but it may be a macro with space-delimited argument. That is, if `<dir>` is an entry in the input path, T<sub>E</sub>X will try to load the expansion of `<dir>{filename}{space}`

So either `<dir>` should be defined as a macro with argument delimited by space, or it should just expand to a directory name, including the final directory separator, so that it may be concatenated with the `<filename>`. This means that for UNIX-like syntax, each `<dir>` should end with a slash, `/`.

`\input@path` should expand to a list of such directories, each in a `{}` group.

`\filename@parse`    After a call of the form: `\filename@parse{<filename>}`, the three macros `\filename@area`, `\filename@base` and `\filename@ext` should be defined to be the ‘area’ (or directory), basename and extension respectively. If there was no extension specified in `<filename>`, `\filename@ext` should be `\let` to `\relax` (so this case may be tested with `\@ifundefined{filename@ext}` and, perhaps a default extension substituted).

Normally one would not need to define this macro in `texsys.cfg` as the automatic tests can supply parsers that work with UNIX and VMS and Macintosh syntax, as well as a basic parser that will cover many other cases. However some operating systems may need a ‘hand produced’ parser in which case it should be defined in this file.

The UNIX parser also works for most MSDOS T<sub>E</sub>X versions. Currently if the UNIX, VMS or Macintosh parser is not used, `\filename@parse` is defined to always return an empty area, and to split the argument into basename and extension at the first ‘.’ that occurs in the name. Parsers for other formats may be defined in `texsys.cfg`, in which case they will be used in preference to the default definitions.

`\@TeXversion`      `\@TeXversion` is now set automatically by the initialization tests in this file. You should not need to set it in `texsys.cfg`, however the following documentation is left for information. L<sup>A</sup>T<sub>E</sub>X does not set this variable exactly, the automatic tests set it to:

2 for any version,  $v$ ,  $v < 3.0$

3 for any version,  $v$ ,  $3.0 \leq v \leq 3.14$

`<undefined>` otherwise.

However these values are accurate enough for L<sup>A</sup>T<sub>E</sub>X to take appropriate action for these old T<sub>E</sub>Xs.

If your T<sub>E</sub>X is older than version 3.141, then you should define `\@TeXversion` (using `\def`) to be the version number. If you do not do this<sup>1</sup>, L<sup>A</sup>T<sub>E</sub>X will not work around a bug in old T<sub>E</sub>X versions, and so error messages will appear in a very strange format, with `^^J` appearing instead of line breaks:

```
LaTeX Error: \rubbish undefined.^^J^^JSee the LaTeX manual or LaTeX=
Companion
for explanation.^^JType  H <return>  for immediate help.
...

.3 \renewcommand{\rubbish}
      {}
```

However if you put `\def\@TeXversion{3.14}` in `texsys.cfg` the following format will be used:

```
LaTeX Error: \rubbish undefined.

ee the LaTeX manual or LaTeX Companion for explanation.
ype  H <return>  for immediate help.
.
...

.3 \renewcommand{\rubbish}
      {}
```

Note that this has an extra line ! . which does not appear in error messages that use the default settings with a current version of T<sub>E</sub>X, but this should not cause any confusion we hope.

## 2 Initialization

As this file is read at a very early stage, some definitions that are normally considered to be part of the format must be made here.

Most such definitions are repeated later in the “right” place, usually (but not always) with different implementations. To be able to spot this more easily if you look into the file `latex.ltx` (which is stripped of comments) we add some comment lines to that effect that survive the stripping process by `docstrip`.

```
1 <*dircheck>
2 %% ---- START temporary definitions for bootstrapping; later overwritten ----
3 </dircheck>
```

---

<sup>1</sup>Actually if your T<sub>E</sub>X is really old, version 2, L<sup>A</sup>T<sub>E</sub>X can detect this, and sets `\@TeXversion` to 2 if it is not set in the `cfg` file.

## 2.1 INITEX

```

4 <*dircheck>
5 <*initex>
6 <initex>\ifnum\catcode'\{=1
7 <initex> \errmessage
8 <initex> {LaTeX must be made using an initex with no format preloaded}
9 <initex>\fi
10 \catcode'\{=1
11 \catcode'\}=2

```

If LuaTeX is in use the extensions and other new primitives have to be activated: this is done as early as possible. Older versions of LuaTeX do not hide the primitives: a version check is not needed as the version itself will be missing in the case where action is needed!

```

12 \ifx\directlua\undefined
13 \else
14 \ifx\luatexversion\undefined

```

Enable e-TeX/pdfTeX/Umath primitives with their natural names

```

15 \directlua{tex.enableprimitives("",%
16 tex.extraprimitives('etex', 'pdfTeX', 'umath'))}

```

In current formats enable primitives with unprefix names. the `latexrelease` guards allow the primitives to be defined with a `\luatex` prefix if older formats are specified.

The unprefix forms are *not* undefined for improved compatibility with external packages when rolling back the format.

```

17 </initex>
18 </dircheck>
19 <*initex, latexrelease>
20 <latexrelease>\ifx\directlua\undefined\else
21 <latexrelease>\IncludeInRelease{2015/10/01}{\luatexluafunction}
22 <latexrelease> {LuaTeX (prefixed names)}%
23 \directlua{tex.enableprimitives("",%
24 tex.extraprimitives("omega", "aleph", "luatex"))}
25 <latexrelease>\EndIncludeInRelease
26 <latexrelease>\IncludeInRelease{0000/00/00}{\luatexluafunction}
27 <latexrelease> {LuaTeX (prefixed names)}%
28 <latexrelease>\directlua{
29 <latexrelease> tex.enableprimitives(
30 <latexrelease> "luatex",
31 <latexrelease> tex.extraprimitives("core","omega", "aleph", "luatex")
32 <latexrelease> )
33 <latexrelease>}
34 <latexrelease>\EndIncludeInRelease
35 <latexrelease>\fi
36 </initex, latexrelease>
37 <*dircheck>
38 <*initex>
39 \fi
40 \fi

```

A test can now be made for eTeX.

```

41 <initex>\ifx\eTeXversion\undefined
42 <initex> \errmessage
43 <initex> {LaTeX requires e-TeX}
44 <initex> \expandafter\endinput

```

```

45 <initex>\fi
    That distraction over, back to the basics of a format.

### 3 texsys.cfg

As mentioned above, any site specific definitions required to describe the filename handling must be entered into a file `texsys.cfg`. If `texsys.cfg` can not be located by `\openin`, we write a default version out. The default version only contains comments, so we do not actually input the file in that case. The automatic tests later will, hopefully, correctly define the required macros.

The tricky code below checks to see if `texsys.cfg` exists. If it does not, all the text in this file between `START` and `END` is copied verbatim to a new file `texsys.cfg`. If `texsys.cfg` is found, then it is simply input. This is only done when this file is being used unstripped.

```

97 <*docstrip>
98 \openin15=texsys.cfg
99 \ifeof15
100 \typeout{** Writing a default texsys.cfg}

```

START

#### 3.1 texsys.cfg

This file contains the site specific definitions of the four macros

`\@currdir`, `\input@path`, `\filename@parse` and `\@TeXversion`.

As distributed it only contains comments, however this ‘empty’ file will work on many systems because of the automatic tests built into `ltdirchk.dtx`. You *are* allowed to edit this file to add definitions of these macros appropriate to your system.

The macros that must be defined are:

`\@currdir`     `\@currdir{filename}<space>` should expand to a form of the filename that uniquely refers to the ‘current directory’ if this is possible. (The expansion should also end with a space.) on UNIX, this is `\def\@currdir{./}`. For more exotic operating systems you may want to make `\@currdir` a macro with arguments delimited by `.` and/or `<space>`. If

the operating system has no concept of directory structure, this macro should be defined to be empty.

`\input@path` If the primitive `\openin` searches the same directories as the primitive `\input`, then it is possible to tell (using `\ifeof`) whether a file exists before trying to input it. For systems like this, `\input@path` should be left undefined.

If `\openin` does not ‘follow’ `\input` then `\input@path` must be defined to be a list of directories to search for input files. The format for each directory is as for `\@currdir`, normally just a prefix is required, but it may be a macro with space-delimited argument. That is, if `<dir>` is an entry in the input path, `TeX` will try to load the expansion of

`<dir><filename><space>`

So either `<dir>` should be defined as a macro with argument delimited by space, or it should just expand to a directory name, including the final directory separator, so that it may be concatenated with the `<filename>`. This means that for UNIX-like syntax, each `<dir>` should end with a slash, `/`. One exception to this rule is that the input path should *always* contain the empty directory `{}` as this will allow ‘full pathnames’ to be used, and the ‘current directory’ to be searched.

`\input@path` should expand to a list of such directories, each in a `{}` group.

`\filename@parse` After a call of the form: `\filename@parse{<filename>}`, the three macros `\filename@area`, `\filename@base`, `\filename@ext` should be defined to be the ‘area’ (or directory), basename and extension respectively. If there was no extension specified in `<filename>`, `\filename@ext` should be `\let` to `\relax` (so this case may be tested with `\@ifundefined{filename@ext}` and, perhaps a default extension substituted).

Normally one would not need to define this macro in `texsys.cfg` as the automatic tests can supply parsers that work with UNIX and VMS syntax, as well as a basic parser that will cover many other cases. However some operating systems may need a ‘hand produced’ parser in which case it should be defined in this file.

The UNIX parser also works for most MSDOS `TeX` versions. Currently if the UNIX or VMS parser is not used, `\filename@parse` is defined to always return an empty area, and to split the argument into basename and extension at the first ‘.’ that occurs in the name. Parsers for other formats may be defined in `texsys.cfg`, in which case they will be used in preference to the default definitions.

`\@TeXversion` You should not need to set this macro in `texsys.cfg`. `LATeX` tests to set this automatically. See the comments in the opening section of `ltdirchk.dtx`.

The following sections give examples of definitions which might work on various systems. These are currently mainly untested as I only have access to a few systems, all of which do not need this file as the automatic tests work. All the code is commented out.

## 3.2 UNIX (web2c)

This implementation does make `\openin` and `\input` look in the same places. Acceptable settings are made by `ltdirchk.dtx`, and so this file may be empty. The definitions below are therefore just for information.

114 `%\def\@currdir{./}`

115 `%\let\input@path\@undefined`

### 3.3 UNIX (other)

Apparently some commercial UNIX implementations have different paths for `\openin` and `\input`. For these one could use definitions like the following (with whatever directories are used at your site): note that the directory names should end with `/`.

```
116 % \def\currdir{./}
117 % \def\input@path{%
118 %   {/usr/local/lib/tex/inputs/distrib/}%
119 %   {/usr/local/lib/tex/inputs/contrib/}%
120 %   {/usr/local/lib/tex/inputs/local/}%
121 % }
```

### 3.4 MSDOS (emtex)

This implementation does make `\openin` and `\input` look in the same places. Acceptable settings are made by `ltdirchk.dtx`, and so this file may be empty. The definitions below are therefore just for information.

```
122 % \def\currdir{./}
123 % \let\input@path\undefined
```

### 3.5 MSDOS (other)

Some PC implementations have different paths for `\openin` and `\input`. For these one could use definitions like the following (with whatever directories are used at your site): note that the directory names should end with `/`. This assumes the implementation uses UNIX style `/` as the directory separator.

```
124 % \def\currdir{./}
125 % \def\input@path{%
126 %   {c:/tex/inputs/distrib/}%
127 %   {c:/tex/inputs/contrib/}%
128 %   {c:/tex/inputs/local/}%
129 % }
```

### 3.6 VMS (DECUS T<sub>E</sub>X, PD VMS 3.6)

This implementation does make `\openin` and `\input` look in the same places. Acceptable settings are made by `ltdirchk.dtx`, and so this file may be empty. The definitions below are therefore just for information.

```
130 % \def\currdir{[] }
131 % \let\input@path\undefined
```

### 3.7 VMS (???)

Some VMS implementations have different paths for `\openin` and `\input`. For these one could use definitions like the following:

```
132 % \def\currdir{[] }
133 % \def\input@path{%
134 %   {tex_inputs:}%
135 %   {SOMEDISK:[SOME.TEXT.DIRECTORY]}%
136 % }
```

### 3.8 MACINTOSH (OzTeX 1.6)

This implementation does make `\openin` and `\input` look in the same places. Acceptable settings are made by `ltdirchk.dtx`, and so this file may be empty. The definitions below are therefore just for information.

```
137 % \def\@currdir{:}
138 % \let\input@path\@undefined
```

### 3.9 MACINTOSH (other)

Some Macintosh implementations have different paths for `\openin` and `\input`. For these one could use definitions like the following (with whatever folders are used on your machine): note that the directory names should end with `:`, and they should contain *no* spaces.

```
139 % \def\@currdir{:}
140 % \def\input@path{%
141 %   {Hard-Disk:Applications:TeX:TeX-inputs:}%
142 %   {Hard-Disk:Applications:TeX:My-inputs:}%
143 % }
```

### 3.10 FAKE EXAMPLE

This example is for an operating system that has filenames of the form `<area>name`. For maximum compatibility with macro sets, you want `name.ext` to be mapped to `<ext>name`, and `<area>name.ext` to be mapped to `<area.ext>name`. `\input` does this mapping automatically, but `\openin` does not, and does not look in the same places as `\input`. `<>name` is the desired ‘current directory’ syntax.

the following code would possibly work:

```
144 % \def\@dir#1#2 {%
145 %   \@d@r{#1}#2..\@nil}
146 % \def\@d@r#1#2.#3.#4\@nil{%
147 %   <\ifx\@dir#1\@dir\else#1\ifx\@dir#3\@dir\else.\fi\fi#3>#2 }
148 %
149 % \def\@currdir{\@dir{}}
150 % \def\input@path{%
151 %   {\@dir{area.one}}}%
152 %   {\@dir{area.two}}}%
153 % }
```

END

```
154 \immediate\closeout15
```

If `texsys.cfg` did exist, then input it.

```
155 \else
156 \typeout{** Using the existing texsys.cfg}
157 \closein15
158 \input texsys.cfg
159 \fi
160 </docstrip>
```

If the stripped version of this file is being used (in `latex2e.ltx`) then `texsys.cfg` should be there, so just input it.

```
161 <dircheck>\input texsys.cfg
```

## 4 Setting \@currdir

`\@currdir` This is a local definition of `\IfFileExists`. It tries to relocate `texsys.aux`. If it succeeds, then the `\@currdir` syntax has been determined. If all the tests fail then `\@currdir` will be set to `\@empty`, and `ltxcheck` will warn of this when it checks the format.

```
162 \begingroup
163 \count@ \time
164 \divide \count@ 60
165 \count2 = - \count@
166 \multiply \count2 60
167 \advance \count2 \time
```

The current date and time stamp.

```
168 \edef \today {%
\today 169 \the \year / \two@digits { \the \month } / \two@digits { \the \day } : %
170 \two@digits { \the \count@ } : \two@digits { \the \count2 }}
```

Create a file `texsys.aux` (hopefully in the current directory), then try to locate it again.

```
171 \immediate \openout15 = texsys.aux
172 \immediate \write15 { \today ^^J }
173 \immediate \closeout15 %
```

`#1` is the file to try, `#2` is what to do on success, `#3` on failure. Note that this definition is overwritten later on again!

```
174 \def \IfFileExists #1#2#3 {%
175 \openin \@inputcheck #1 %
176 \ifeof \@inputcheck
177 #3 \relax
178 \else
179 \read \@inputcheck to \reserved@a
180 \ifx \reserved@a \today
181 \typeout { #1 found } #2 \relax
182 \else
183 \typeout { BAD: old file \reserved@a (should be \today) } %
184 #3 \relax
185 \fi
186 \fi
187 \closein \@inputcheck }
188 \endlinechar = -1
```

If `\@currdir` has not been pre-defined in `texsys.cfg` then test for UNIX, VMS and Oz-TeX-Mac. syntax.

```
189 \ifx \@currdir \@undefined
190 \IfFileExists { ./texsys.aux } { \gdef \@currdir { ./ } } %
191 { \IfFileExists { [] texsys.aux } { \gdef \@currdir { [] } } %
192 { \IfFileExists { : texsys.aux } { \gdef \@currdir { : } } { } }
```

If it is still undefined at this point, all the above tests failed. Earlier versions interactively prompted for a definition at this point, but it seems impossible to reliably obtain information from users at this point in the installation. This version of the file produces

a format with no user-interaction. Later if the format is not suitable for the system, `texsys.cfg` may be edited and the format re-made.

```

193 \ifx\@currdir\undefined
194 \global\let\@currdir\empty
195 \typeout{^^J^^J%
196     !! No syntax for the current directory could be found^^J%
197 }%
198 \fi

```

Otherwise `\@currdir` was defined in `texsys.cfg`. In this case check that the syntax specified works on this system. (In case a complete  $\text{\LaTeX}$  system has been copied from one system to another.) If the test fails, give up. The installer should remove or correct the offending `texsys.cfg` and try again.

```

199 \else
200 \IfFileExists{\@currdir texsys.aux}{\}%
201 \edef\reserved@a{\errhelp{%
202     texsys.cfg specifies the current directory syntax to be^^J%
203     \meaning\@currdir^^J%
204     but this does not work on this system.^^J%
205     Remove texsys.cfg and restart.}}\reserved@a
206 \errmessage{Bad texsys.cfg file: \noexpand\@currdir}\@@end}

```

The version of `\@currdir` in `texsys.cfg` looks OK.

```

207 \fi

208 \immediate\closeout15 %
209 \endgroup

210 \typeout{^^J^^J%
211     \noexpand\@currdir set to:
212     \expandafter\strip@prefix\meaning\@currdir.^^J%
213 }

```

*(End of definition for \@currdir, \IfFileExists, and \today.)*

Stop here if the file is being used unstripped.

```

214 <docstrip>
215 \relax\endinput
216 </docstrip>

```

## 5 Setting `\input@path`

Earlier versions of this file attempted to automatically test whether `\input@path` was required, and interactively prompt for a path if necessary. This was not found to be very reliable. The first-time installer of  $\text{\LaTeX} 2_{\epsilon}$  can not be expected to have enough information to supply the correct information to the prompts. Now the interaction is omitted. After the format is made the installer can attempt to run the test document `ltxcheck.tex` through  $\text{\LaTeX} 2_{\epsilon}$ . This will check, among other things, whether `texsys.cfg` will need to be edited and the format remade.

`\input@path` Now set up the `\input@path`.

`\input@path` should either be undefined, or a list of directories as described in the introduction.

```

217 \typeout{^^J%

```

```

218     Assuming \noexpand\openin and \noexpand\input^^J%
219     \ifx\input@path\@undefined
\input@path has not been pre-defined.
220         have the same search path.^^J%
221     \else
\input@path has been defined in texsys.cfg.
222         have different search paths.^^J%
223         LaTeX will use the path specified by \noexpand\input@path:^^J%
224     \fi
225 }

(End of definition for \input@path.)

```

## 6 Filename Parsing

`\filename@parse` Split a filename into its components.

```

226 \ifx\filename@parse\@undefined
227     \def\reserved@a{.}\ifx\@currdir\reserved@a
\filename@parse was not specified in texsys.cfg, but \@currdir looks like UNIX...

301 </dircheck,latexrelease>
302 <*dircheck>

      Remove a final dot, added earlier.
303   \def\filename@dot#1.\{#1}

304   \else

Otherwise, \filename@parse was specified in texsys.cfg.
305   \typeout{^^J^^J%
306     \noexpand\filename@parse was defined in texsys.cfg:^^J%
307     \expandafter\strip@prefix\meaning\filename@parse.^^J%
308   }
309   \fi

(End of definition for \filename@parse.)

```

## 7 T<sub>E</sub>X Versions

`\TeXversion` T<sub>E</sub>X versions older than 3.141 require `\TeXversion` to be set. This can be determined automatically due to a trick suggested by Bernd Raichle. Actually this will not always get the correct version number, e.g., T<sub>E</sub>X3.14 would be detected as T<sub>E</sub>X3, but L<sup>A</sup>T<sub>E</sub>X only needs to take account of T<sub>E</sub>X's older than 3, or between 3 and 3.14.

```

310 \ifx\TeXversion\@undefined
311   \ifx\@undefined\inputlineno
312     \def\TeXversion{2}
313   \else
314     {\catcode'\^^J=\active
315      \def\reserved@a#1#2\@{\if#1\string^3\fi}
316      \edef\reserved@a{\expandafter\reserved@a\string^^J\@}
317      \ifx\reserved@a\@empty\else\gdef\TeXversion{3}\fi}
318   \fi
319 \fi

(End of definition for \TeXversion.)

320 %% ---- END temporary definitions for bootstrapping ----
321 </dircheck>

```

## 8 ltxcheck.tex

After the format has been made, and `article.cls` moved with the other files to the ‘standard input directory’ as specified in `install.txt`, the format may be checked by running the file `ltxcheck.tex`.

## File 02

# lplain.dtx

## 1 Plain T<sub>E</sub>X

L<sup>A</sup>T<sub>E</sub>X includes almost all of the functionality of Knuth's original 'Basic Macros' That is, the plain T<sub>E</sub>X format described in Appendix B of the T<sub>E</sub>XBook. However, some of the user commands are not much use so, in order to save memory, we may remove them from the kernel into a package. Here is a list of the commands that may be removed (PROBABLY NOT COMPLETE).

```
\magstep      \magstephalf
\mathhexbox
\vglue        \vgl@
\hglue        \hgl@
```

This file is by now very small as most of it has been moved to more appropriate kernel files: it may disappear completely one day.

L<sup>A</sup>T<sub>E</sub>X font definitions are done using NFSS2 so none of PLAIN's font definitions are in L<sup>A</sup>T<sub>E</sub>X.

L<sup>A</sup>T<sub>E</sub>X has its own tabbing environment, so PLAIN's is disabled.

L<sup>A</sup>T<sub>E</sub>X uses its own output routine, so most of the plain one was removed.

```
1 (*2kernel)
2 \catcode'\{=1 % left brace is begin-group character
3 \catcode'\}=2 % right brace is end-group character
4 \catcode'\$=3 % dollar sign is math shift
5 \catcode'\&=4 % ampersand is alignment tab
6 \catcode'\#=6 % hash mark is macro parameter character
7 \catcode'\^=7 % circumflex and uparrow are for superscripts
8 \catcode'\_ =8 % underline and downarrow are for subscripts
9 \catcode'\^~I=10 % ascii tab is a blank space
10 \chardef\active=13 \catcode'\~=\active % tilde is active
11 \catcode'\^~L=\active \def^~L{\par}% ascii form-feed is \par
12 \message{catcodes,}
```

We had to define the \catcodes right away, before the message line, since \message uses the { and } characters. When INITEX (the T<sub>E</sub>X initializer) starts up, it has defined the following \catcode values:

```
\catcode'\^~@=9 %  ascii null is ignored
\catcode'\^~M=5 %  ascii return is end-line
\catcode'\ =0 %    backslash is TeX escape character
\catcode'\%=14 %   percent sign is comment character
\catcode'\ =10 %   ascii space is blank space
\catcode'\^~?=15 %  ascii delete is invalid
\catcode'\A=11 ... \catcode'\Z=11 % uppercase letters
\catcode'\a=11 ... \catcode'\z=11 % lowercase letters
all others are type 12 (other)
```

Here is a list of the characters that have been specially catcoded:

```
13 \def\dospecials{\do\ \do\\\do\{\do\}\do\$\do\&%
14   \do\#\do\^~\do\_ \do\% \do\~ \do\^~I}
```

(not counting ascii null, linefeed, formfeed, return, delete) Each symbol in the list is preceded by , which can be defined if you want to do something to every item in the list.

We make @ signs act like letters, temporarily, to avoid conflict between user names and internal control sequences of plain format.

```
15 \catcode'\@=11
```

To make the plain macros more efficient in time and space, several constant values are declared here as control sequences. If they were changed, anything could happen; so they are private symbols.

`\@ne` Small constants are defined using `\chardef`.

```
\tw@ 16 \chardef\@ne=1
\thr@@ 17 \chardef\tw@=2
\sixt@@n 18 \chardef\thr@@=3

Allocation of registers

Here are macros for the automatic allocation of `\count`, `\box`, `\dimen`, `\skip`, `\muskip`, and `\toks` registers, as well as `\read` and `\write` stream numbers, `\fam` codes, `\language` codes, and `\insert` numbers.

```
25 \message{registers,}
```

When a register is used only temporarily, it need not be allocated; grouping can be used, making the value previously in the register return after the close of the group. The main use of these macros is for registers that are defined by one macro and used by others, possibly at different nesting levels. All such registers should be defined through these macros; otherwise conflicts may occur, especially when two or more macro packages are being used at the same time.

*Historical L<sup>A</sup>T<sub>E</sub>X 2.09 comments (not necessarily accurate any more):*

The following counters are reserved:

- 0 to 9 page numbering
- 10 count allocation
- 11 dimen allocation
- 12 skip allocation
- 13 muskip allocation
- 14 box allocation
- 15 toks allocation
- 16 read file allocation
- 17 write file allocation
- 18 math family allocation
- 19 language allocation
- 20 insert allocation
- 21 the most recently allocated number

22 constant -1

*End of historical L<sup>A</sup>T<sub>E</sub>X 2.09 comments.*

New counters are allocated starting with 23, 24, etc. Other registers are allocated starting with 10. This leaves 0 through 9 for the user to play with safely, except that counts 0 to 9 are considered to be the page and subpage numbers (since they are displayed during output). In this scheme, `\count 10` always contains the number of the highest-numbered counter that has been allocated, `\count 14` the highest-numbered box, etc. Inserts are given numbers 254, 253, etc., since they require a `\count`, `\dimen`, `\skip`, and `\box` all with the same number; `\count 20` contains the lowest-numbered insert that has been allocated. Of course, `\box255` is reserved for `\output`; `\count255`, `\dimen255`, and `\skip255` can be used freely.

It is recommended that macro designers always use `\global` assignments with respect to registers numbered

1, 3, 5, 7, 9,

and always non-`\global` assignments with respect to registers

0, 2, 4, 6, 8, 255.

This will prevent “save stack buildup” that might otherwise occur.

```
26 \count10=22 % allocates \count registers 23, 24, ...
27 \count11=9 % allocates \dimen registers 10, 11, ...
28 \count12=9 % allocates \skip registers 10, 11, ...
29 \count13=9 % allocates \muskip registers 10, 11, ...
30 \count14=9 % allocates \box registers 10, 11, ...
31 \count15=9 % allocates \toks registers 10, 11, ...
32 \count16=-1 % allocates input streams 0, 1, ...
33 \count17=-1 % allocates output streams 0, 1, ...
34 \count18=3 % allocates math families 4, 5, ...
35 \count19=0 % allocates \language codes 1, 2, ...
36 \count20=255 % allocates insertions 254, 253, ...
```

`\insc@unt` The insertion counter and most recent allocation.

```
\allocationnumber
37 \countdef\insc@unt=20
38 \countdef\allocationnumber=21
```

```

```
\toks@
45 \skipdef\skip@=0
```

```
46 \toksdef\toks@=0
```

(End of definition for \count@ and others.)

\newcount Now, we define \newcount, \newbox, etc. so that you can say \newcount\foo and \foo  
 \newdimen will be defined (with \countdef) to be the next counter.  
 \newskip To find out which counter \foo is, you can look at \allocationnumber.  
 \newmuskip Since there's no \boxdef command, \chardef is used to define a \newbox,  
 \newbox \newinsert, \newfam, and so on.  
 \newtoks L<sup>A</sup>T<sub>E</sub>X change: remove \outer from \newcount and \newdimen (FMi) This is nec-  
 \newread essary to use \newcount inside \if... later on. Also remove from \newskip, \newbox  
 \newwrite \newwrite and \newfam (DPC) to save later redefinition. Rolling back the allocation  
 \newfam routine runs us into trouble nowadays as the kernel itself will use up all of the standard  
 \newlanguage pool. So we pretend we've always used the full range: this is needed for roll forward.

```

47 \def\newcount {\e@alloc\count \countdef {\count10}\insc@unt\float@count}
48 \def\newdimen {\e@alloc\dimen \dimendef {\count11}\insc@unt\float@count}

```

*(End of definition for \e@ch@ck, \extrafloats, and \extrafloats.)*

`\alloc@` Since `\e@alloc` was added in 2015, `\@alloc` has not been used, but was left as some legacy code calls it. However the original definition gives spurious errors once the “classic” registers run out, so it is now defined to call `\e@alloc` internally.

```
141 \def\alloc@#1#2#3#4{\e@alloc#2#3{\count1#1}#4\float@count}
```

*(End of definition for \alloc@.)*

`\newinsert` The highest register allowed with `\insert`.

```

```

In the past L<sup>A</sup>T<sub>E</sub>X used the default value of 1 for `\tracinglostchars` because this was the best it could do. This way one would at least get a warning in the `.log` file. e-T<sub>E</sub>X improved on that and supported a value of 2 to show the warning on the terminal, so we could have changed the default when we made the e-T<sub>E</sub>X extensions required—however, we overlooked that opportunity. In 2021 this parameter was improved on again and now also accepts the value 3 (error on the terminal). This made us realize that we should change the default. Using 3 would really be the best, but for compatibility reasons we only use 2. For recent LuaT<sub>E</sub>X releases, we set 4: this is offset by 2 from the e-T<sub>E</sub>X value as otherwise LuaT<sub>E</sub>X only issues a warning for text in a box when the box is used, not saved. (Accepting values of 4 and 5 was updated in the T<sub>E</sub>X Live 2025 release.)

```

216 \tracinglostchars=2

                      311 \baselineskip\normalbaselineskip \lineskiplimit\normallineskiplimit}

(End of definition for \normalbaselines.)

\M Save a bit of space by using \let here.
\I  312 \def\^M{\ } % control <return> = control <space>
    313 \let\^I\^M % same for <tab>

(End of definition for \M and \I.)

\lq
\rq  314 \def\lq{' }
    315 \def\rq{' }

```

(End of definition for `\lq` and `\rq`.)

`\lbrack`  
`\rbrack`    316 `\def\lbrack{[}`  
                   317 `\def\rbrack{]}`

(End of definition for `\lbrack` and `\rbrack`.)

`\aa`    These are not from plain.tex but they are similar to other commands found here and  
`\AA`    nowhere else, being alternate input forms for characters.

          318 `\def \aa {\r a}`  
           319 `\def \AA {\r A}`

(End of definition for `\aa` and `\AA`.)

**`\endgraf`**  
`\endline`    320 `\let\endgraf=\par`  
                   321 `\let\endline=\cr`

(End of definition for `\endgraf` and `\endline`. These functions are documented on page 417.)

`\space`

          322 `\def\space{ }`

(End of definition for `\space`.)

`\empty`    This probably ought to go altogether, but let it to the L<sup>A</sup>T<sub>E</sub>X version to save space.

          323 `\let\empty\@empty`

(End of definition for `\empty`.)

`\null`

          324 `\def\null{\hbox{}}`

(End of definition for `\null`.)

`\bgroup`  
`\egroup`    325 `\let\bgroup={`  
                   326 `\let\egroup=}`

(End of definition for `\bgroup` and `\egroup`.)

`\obeylines`    In `\obeylines`, we say `\let^M=\obeyedline` instead of `\def^M{\obeyedline}` since  
`\obeyspaces`    this allows, for example, `\let\obeyedline=\cr \obeylines \halign{...`

          This is essentially a plain T<sub>E</sub>X trick and in its original version where you had to use  
           to use `\let\par=\cr` not really a safe idea in L<sup>A</sup>T<sub>E</sub>X. If anybody used this trick this now  
           breaks (and one needs to use `\obeyedline` instead).

          327 `\</2ekernel>`  
           328 `\<*2ekernel | latexrelease>`  
           329 `\<latexrelease>\IncludeInRelease{2022/06/01}{\obeylines}%`  
           330 `\<latexrelease>    {Add a redirection to obeylines and obeyspaces}%`

If the active `^^M` escapes, e.g., into a `\write` (which is effectively in a different context) then we don't want the definition from `\obeylines` but rather a simple `\par` (in fact even the primitive one, not the L<sup>A</sup>T<sub>E</sub>X version `\para_end`: which is only defined later).

```
331 \begingroup
332 \catcode'\^^M=\active % these lines must end with %
333 \gdef\obeylines{\catcode'\^^M\active%
334 \let^^M\obeyedline%
```

The next line ending the definition is rather curious and it took me awhile to understand why rollback fails. The problem is the following: if `latexrelease` is used, then blocks of `\IncludeInRelease ... \EndIncludeInRelease` are bypassed at high speed by grabbing each as a delimited argument. However, in that case `^^M` is seen not as code but as line ending characters and in that mode T<sub>E</sub>X discards everything from that point onwards to the real end of the line so it works like a comment — pretty strange really (and I think due to the fact that the original pascal compiler could have some garbage showing up after the normal line ending character. Thus we really have to make sure that any closing braces is not one the same line as an `^^M`, because otherwise it would get dropped and we end with unbalanced braces and never see the `\EndIncludeInRelease` — weird. In other places it doesn't matter because we aren't using the incomplete result.

```
335 }%
336 \global\let^^M\par % this is in case ^^M appears in a \write
337 \endgroup
```

The `\obeyedline` expands by default to `\par` with whatever definition `\par` has when it is executed. It can, however, be redefined (before calling `\obeylines`!) to achieve some special effects. If you want to alter this definition when already in the scope of `\obeylines`, it has no effect (because `\let` is used above). In that case simply make another call to `\obeylines` immediately. As you are in a restricted scope all that happens is that your redefinition is applied.

For the default definition we have to use `\def` not `\let` because the meaning of `\par` can change and we want to use the one that is current when `\obeylines` act.

There is a small subtlety here: in an `\edef` the active `^^M` stayed put (because it was equal to the primitive `\par`), now `\obeyedline` expands and you get what it contains, i.e., in that case `\par`, into the `\edef` or `\mark` unless we use `\protected` on it.

```
338 \protected\gdef\obeyedline{\par}
```

The definition of `\obeyspaces` is changed in the same way and now executes `\obeyedspace` for each active space.

```
\obeyedspace 339 \global\let\obeyedspace\space

340 \begingroup
341 \catcode'\ =\active%
342 \gdef\obeyspaces{\catcode'\ \active\let =\obeyedspace}%

```

An active space elsewhere generates `\space` by default (for example in a `\write`).

```
343 \global\let =\space%
344 \endgroup

345 </2ekernel | latexrelease>
346 <latexrelease>\EndIncludeInRelease
347 <latexrelease>\IncludeInRelease{0000/00/00}{\obeylines}%
348 <latexrelease> {Add a redirection to obeylines and obeyspaces}%
349 <latexrelease>
```

From 2019 onwards the commands are made robust (somewhat later in the kernel sources). So if we roll back they are robust, so when redefining them we have get rid of the robust payload first. Otherwise that is seen by the later rollback below, which then installs a fragile version of the new definition on top of the one we roll back to here, sigh. `\kernel@make@fragile` also changes its definition (later own) so this is done directly.

```
350 <latexrelease>\expandafter\let\csname obeylines \endcsname \@undefined
351 <latexrelease>\expandafter\let\csname obeyspace \endcsname \@undefined
352 <latexrelease>
353 <latexrelease>\begingroup
354 <latexrelease>\catcode'\^M=\active % these lines must end with %
355 <latexrelease> \gdef\obeylines{\catcode'\^M\active \let^M\par %
```

Closing brace on a separate line (see comment above).

```
356 <latexrelease> }%
```

Another pitfall: if we do a rollback `\par` is no longer the primitive, so the roll back definition needs `\let` to what is new the primitive.

```
357 <latexrelease> \global\let^M\RawParEnd % this is in case ^M appears in a \write
358 <latexrelease>\endgroup
359 <latexrelease>\def\obeyspaces{\catcode'\ \active}
360 <latexrelease>
361 <latexrelease>\let\obeyedline\@undefined
362 <latexrelease>\let\obeyedspace\@undefined
363 <latexrelease>\EndIncludeInRelease
364 <*2ekernel>
```

*(End of definition for \obeylines and others.)*

`\loop` We use Kabelschacht's method of doing loops, see TUB 8#2 (1987). (unless that breaks something :-). It turned out to need an extra `\relax`: see pr/642 (`\loop` could do one iteration too much in certain cases).

```
365 \long\def \loop #1\repeat{%
366   \def\iterate{#1\relax % Extra \relax
367     \expandafter\iterate\fi
368   }%
369   \iterate
370   \let\iterate\relax
371 }
```

This setting of `\repeat` is needed to make `\loop...\if...\repeat` skippable within another `\if...`

```
372 \let\repeat=\fi
```

*(End of definition for \loop, \iterate, and \repeat.)*

L<sup>A</sup>T<sub>E</sub>X defines `\smallskip`, etc. in `ltspace.dtx`.

```
\nointerlineskip
\offinterlineskip
373 \def\nointerlineskip{\prevdepth-\@m\p@}
374 \def\offinterlineskip{\baselineskip-\@m\p@
375   \lineskip\z@ \lineskiplimit\maxdimen}
```

*(End of definition for \nointerlineskip and \offinterlineskip.)*

```

\vglue
\hglue 376 \def\vglue{\afterassignment\vgl@\skip@=}
377 \def\vgl@{\par \dimen@\prevdepth \hrule \@height\z@
378 \nobreak\vskip\skip@ \prevdepth\dimen@}
379 \def\hglue{\afterassignment\hgl@\skip@=}
380 \def\hgl@{\leavevmode \count@\spacefactor \vrule \@width\z@
381 \nobreak\hskip\skip@ \spacefactor\count@}

(End of definition for \vglue and \hglue.)
LATEX defines ~ in ltdefs.dtx.

\slash This generates a / acting a bit like - but still allows hyphenation in the word part
preceding it (but not after).
382 \def\slash{/\penalty\exhyphenpenalty}

(End of definition for \slash.)

\break
\nobreak 383 \def\break{\penalty-\@M}
\allowbreak 384 \def\nobreak{\penalty \@M}
385 \def\allowbreak{\penalty \z@}

(End of definition for \break, \nobreak, and \allowbreak.)

\filbreak
\goodbreak 386 \def\filbreak{\par\vfil\penalty-200\vfilneg}
387 \def\goodbreak{\par\penalty-500 }

(End of definition for \filbreak and \goodbreak.)

\eject Define \eject as in plain TEX but define \supereject only in the compatibility file.
388 \def\eject{\par\break}

(End of definition for \eject.)

\removelastskip
389 \def\removelastskip{\ifdim\lastskip=\z@\else\vskip-\lastskip\fi}

(End of definition for \removelastskip.)

\smallbreak
\medbreak 390 \def\smallbreak{\par\ifdim\lastskip<\smallskipamount
\removelastskip\penalty-50\smallskip\fi}
\bigbreak 391 \def\medbreak{\par\ifdim\lastskip<\medskipamount
\removelastskip\penalty-100\medskip\fi}
392 \def\bigbreak{\par\ifdim\lastskip<\bigskipamount
\removelastskip\penalty-200\bigskip\fi}
393
394
395

(End of definition for \smallbreak, \medbreak, and \bigbreak.)

\m@th
396 \def\m@th{\mathsurround\z@}

(End of definition for \m@th.)

```

`\underbar` Due to L<sup>A</sup>T<sub>E</sub>X's redefinition of `\underline` plain T<sub>E</sub>X's `\underbar` can be done in a simpler fashion (but do we need it at all?).

```

397 \def\underbar#1{\underline{\sbox\tw@{#1}\dp\tw@z@ \box\tw@}}

```

(End of definition for `\underbar`.)

`\strutbox` L<sup>A</sup>T<sub>E</sub>X sets `\strutbox` in `\set@fontsize`.

```

\strut
398 \newbox\strutbox
399 \def\strut{\relax\ifmmode\copy\strutbox\else\unhcopy\strutbox\fi}

```

(End of definition for `\strutbox` and `\strut`.)

`\hidewidth` For alignment entries that can stick out.

```

400 \def\hidewidth{\hskip\hideskip}

```

(End of definition for `\hidewidth`.)

`\narrower`

```

401 \def\narrower{%
402   \advance\leftskip\parindent
403   \advance\rightskip\parindent}

```

(End of definition for `\narrower`.)

L<sup>A</sup>T<sub>E</sub>X defines `\ae` and similar commands elsewhere.

```

404 \chardef\%= '\%
405 \chardef\&= '\&
406 \chardef\#= '\#

```

Most text commands are actually encoding specific and therefore defined later, so commented out or removed from this file.

`\leavevmode` begins a paragraph, if necessary

```

407 \def\leavevmode{\unhbox\voidb@x}

```

(End of definition for `\leavevmode`.)

`\mathhexbox`

```

408 \def\mathhexbox#1#2#3{\mbox{$\m@th \mathchar"#1#2#3$}}

```

(End of definition for `\mathhexbox`.)

`\ialign`

```

409 \def\ialign{\everycr{}\tabskipz@skip\halign} % initialized \halign

```

(End of definition for `\ialign`.)

`\oalign`

```

\o@lign
410 \def\oalign#1{\leavevmode\vtop{\baselineskipz@skip \lineskip.25ex%
\oalign
411   \ialign{##\crrc#1\crrc}}}
412 \def\o@lign{\lineskiplimitz@ \oalign}
413 \def\oalign{\lineskiplimit-\maxdimen \oalign}

```

(End of definition for `\oalign`, `\o@lign`, and `\oalign`.)

`\sh@ft` The definition of this macro in plain.tex was improved in about 1997; but as a result its usage was changed and its new definition is not appropriate for L<sup>A</sup>T<sub>E</sub>X.

Since the version given here has been in use by L<sup>A</sup>T<sub>E</sub>X for many years it does not seem prudent to remove it now. As far as we can tell it has only been used to define `\b` and `\d` but this cannot be certain.

```
414 \def\sh@ft#1{\dimen@.00#1ex\multiply\dimen@\fontdimen1\font
415 \kern-.0156\dimen@} % compensate for slant in lowered accents
```

*(End of definition for \sh@ft.)*

`\ltx@sh@ft` This is the L<sup>A</sup>T<sub>E</sub>X version of the second incarnation of the plain macro `\sh@ft`, which takes a dimension as its argument. It shifts a pseudo-accent horizontally by an amount proportional to the product of its argument and the slant-per-point (`fontdimen 1`).

```
416 \def\ltx@sh@ft #1{%
417 \dimen@ #1%
418 \kern \strip@pt
419 \fontdimen1\font \dimen@
420 } % kern by #1 times the current slant
```

*(End of definition for \ltx@sh@ft.)*

L<sup>A</sup>T<sub>E</sub>X change: the text commands such as `\d`, `\b`, `\c`, `\copyright`, `\TeX` are now defined elsewhere.

L<sup>A</sup>T<sub>E</sub>X change: Make `\t` work in a moving argument. Now defined elsewhere.

`\hrulefill` L<sup>A</sup>T<sub>E</sub>X change: `\kern\z@` added to end of `\hrulefill` and `\dotfill` to make them work  
`\dotfill` in ‘tabular’ and ‘array’ environments. (Change made 24 July 1987). L<sup>A</sup>T<sub>E</sub>X change: `\leavevmode` added at beginning of `\dotfill` and `\hrulefill` so that they work as expected in vertical mode.

```
421 \def\hrulefill{\leavevmode\leaders\hrule\hfill\kern\z@}
```

The box in `\dotfill` originally contained (in plain.tex):

```
\mkern 1.5mu .\mkern 1.5mu;
```

the width of .44em differs from this by .04pt which is probably an acceptable difference within leaders.

```
422 \def\dotfill{%
423 \leavevmode
424 \cleaders \hb@xt@ .44em{\hss.\hss}\hfill
425 \kern\z@}
```

*(End of definition for \hrulefill and \dotfill.)*

INITEX sets `\sfcode x=1000` for all x, except that `\sfcode X=999` for uppercase letters. The following changes are needed:

```
426 \sfcode'\)=0 \sfcode'\ '=0 \sfcode'\]=0
```

The `\nonfrenchspacing` macro will make further changes to `\sfcode` values.

Definitions related to output

`\magnification` doesn’t work in L<sup>A</sup>T<sub>E</sub>X.

```
def\magnification{\afterassignment\m@g\count@}
def\m@g{\mag\count@
\hsize6.5truein\vsizer8.9truein\dimen\footins8truein}
```

`\showoverfull` The following commands are used in debugging:

```
427 \def\showoverfull{\tracingonline\@ne}
```

(End of definition for \showoverfull.)

```
\showoutput
\loggingoutput 428 \gdef\loggingoutput{\tracingoutput\@ne
429 \showboxbreadth\maxdimen\showboxdepth\maxdimen\errorstopmode}
430 \gdef\showoutput{\loggingoutput\showoverfull}
431 \endkernel
```

(End of definition for \showoutput and \loggingoutput.)

## File 03

# ltvers.dtx

## 1 Version Identification

First we identify the date and version number of this release of L<sup>A</sup>T<sub>E</sub>X, and set `\everyjob` so that it is printed at the start of every L<sup>A</sup>T<sub>E</sub>X run.

`\fmtname` A `\patch@level` of 0 or higher denotes an official public release. A negative value indicates a candidate release that is not distributed.

`\fmtversion`

`\latexreleaseversion` If we put code updates into the kernel that are supposed to go into the next release we set the `\patch@level` to -1 and the `\fmtversion` / `\latexreleaseversion` to the dated of the next release (guessed, the real value is not so important and will get corrected when we make the release official).

`\patch@level`

If the `\patch@level` is already at -1 we do nothing here and use the `\fmtversion` date for any new `\IncludeInRelease` line when we add further code.

Finally, if we do make a public release we either just set the `\patch@level` to zero (if our initial guess was good) or we also change the date and then have to additionally change to that date on all the `\IncludeInRelease` statements that used the “guessed” date.

```

10 \def\patch@level{0}
```

For more fine grain control there is the possibility to name the current development branch. This is only used when the `\patch@level` is negative (i.e., a pre-release format) and is intended to help us internally when we locally install a format out of some development branch.

```
\development@branch@name 11 \edef\development@branch@name{develop \the\year-\the\month-\the\day}
```

*(End of definition for `\fmtname` and others.)*

Check that the format being made is not too old. The error message complains about ‘more than 5 years’ but in fact the error is not triggered until 65 months.

This code is currently not activated as we don’t know if we already got to the last official 2e version (due to staff shortage or due to a successor (think positive:-)).

```
12 \iffalse
13 \def\reserved@a#1/#2/#3\@nil{%
14   \count@ \year
15   \advance\count@-#1\relax
16   \multiply\count@ by 12\relax
17   \advance\count@\month
18   \advance\count@-#2\relax}
19 \expandafter\reserved@a\fmtversion\@nil
```

\count@ is now the age of this file in months. Take a generous definition of ‘year’ so this message is not generated too often.

```

## File 04

# lualatex.dtx

## 1 Overview

LuaTeX adds a number of engine-specific functions to TeX. Several of these require set up that is best done in the kernel or need related support functions. This file provides *basic* support for LuaTeX at the L<sup>A</sup>T<sub>Ε</sub>X 2<sub>ε</sub> kernel level plus as a loadable file which can be used with plain TeX and L<sup>A</sup>T<sub>Ε</sub>X.

This file contains code for both TeX (to be stored as part of the format) and Lua (to be loaded at the start of each job). In the Lua code, the kernel uses the namespace `luatexbase`.

The following `\count` registers are used here for register allocation:

```
\e@alloc@attribute@count Attributes (default 258)
\e@alloc@ccodetable@count Category code tables (default 259)
\e@alloc@luafunction@count Lua functions (default 260)
  \e@alloc@whatsit@count User whatsits (default 261)
  \e@alloc@bytecode@count Lua bytecodes (default 262)
  \e@alloc@luachunk@count Lua chunks (default 263)
```

(`\count 256` is used for `\newmarks` allocation and `\count 257` is used for `\newXeTeXintercharclass` with XeTeX, with code defined in `ltxfinal.dtx`). With any L<sup>A</sup>T<sub>Ε</sub>X 2<sub>ε</sub> kernel from 2015 onward these registers are part of the block in the extended area reserved by the kernel (prior to 2015 the L<sup>A</sup>T<sub>Ε</sub>X 2<sub>ε</sub> kernel did not provide any functionality for the extended allocation area).

## 2 Core TeX functionality

The commands defined here are defined for possible inclusion in a future L<sup>A</sup>T<sub>Ε</sub>X format, however also extracted to the file `lualatex.tex` which may be used with older L<sup>A</sup>T<sub>Ε</sub>X formats, and with plain TeX.

```
\newattribute \newattribute{<attribute>}
  Defines a named \attribute, indexed from 1 (i.e. \attribute0 is never defined). Attributes initially have the marker value -7FFFFFFF ('unset') set by the engine.
\newcatcodetable \newcatcodetable{<catcodetable>}
  Defines a named \catcodetable, indexed from 1 (\catcodetable0 is never assigned). A new catcode table will be populated with exactly those values assigned by IniTeX (as described in the LuaTeX manual).
\newluafunction \newluafunction{<function>}
  Defines a named \luafunction, indexed from 1. (Lua indexes tables from 1 so \luafunction0 is not available).
\newluacmd \newluacmd{<function>}
  Like \newluafunction, but defines the command using \luadef instead of just assigning an integer.
```

<code>\newprotectedluacmd</code>	<code>\newluaundef{&lt;function&gt;}</code>	Like <code>\newluacmd</code> , but the defined command is not expandable.
<code>\newwhatsit</code>	<code>\newwhatsit{&lt;whatsit&gt;}</code>	Defines a custom <code>\whatsit</code> , indexed from 1.
<code>\newluabytecode</code>	<code>\newluabytecode{&lt;bytecode&gt;}</code>	Allocates a number for Lua bytecode register, indexed from 1.
<code>\newluachunkname</code>	<code>newluachunkname{&lt;chunkname&gt;}</code>	Allocates a number for Lua chunk register, indexed from 1. Also enters the name of the register (without backslash) into the <code>lua.name</code> table to be used in stack traces.
<code>\catcodetable@initex</code>	Predefined category code tables with the obvious assignments. Note that the <code>latex</code> and	
<code>\catcodetable@string</code>	<code>atletter</code> tables set the full Unicode range to the codes predefined by the kernel.	
<code>\catcodetable@latex</code>	<code>\setattribute{&lt;attribute&gt;}{&lt;value&gt;}</code>	
<code>\catcodetable@atletter</code>	<code>\unsetattribute{&lt;attribute&gt;}</code>	
<code>\setattribute</code>	Set and unset attributes in a manner analogous to <code>\setlength</code> . Note that attributes	
<code>\unsetattribute</code>	take a marker value when unset so this operation is distinct from setting the value to zero.	

### 3 Plain T<sub>E</sub>X interface

The `luatex` interface may be used with plain T<sub>E</sub>X using `\input{luatex}`. This inputs `luatex.tex` which inputs `etex.src` (or `etex.sty` if used with L<sup>A</sup>T<sub>E</sub>X) if it is not already input, and then defines some internal commands to allow the `luatex` interface to be defined.

The `luatexbase` package interface may also be used in plain T<sub>E</sub>X, as before, by inputting the package `\input luatexbase.sty`. The new version of `luatexbase` is based on this `luatex` code but implements a compatibility layer providing the interface of the original package.

## 4 Lua functionality

### 4.1 Allocators in Lua

<code>new_attribute</code>	<code>luatexbase.new_attribute(&lt;attribute&gt;)</code>	Returns an allocation number for the <code>&lt;attribute&gt;</code> , indexed from 1. The attribute will be initialised with the marker value <code>-"7FFFFFFF</code> ('unset'). The attribute allocation sequence is shared with the T <sub>E</sub> X code but this function does <i>not</i> define a token using <code>\attributedef</code> . The attribute name is recorded in the <code>attributes</code> table. A metatable is provided so that the table syntax can be used consistently for attributes declared in T <sub>E</sub> X or Lua.
<code>new_whatsit</code>	<code>luatexbase.new_whatsit(&lt;whatsit&gt;)</code>	Returns an allocation number for the custom <code>&lt;whatsit&gt;</code> , indexed from 1.
<code>new_bytecode</code>	<code>luatexbase.new_bytecode(&lt;bytecode&gt;)</code>	Returns an allocation number for a bytecode register, indexed from 1. The optional <code>&lt;name&gt;</code> argument is just used for logging.
<code>new_chunkname</code>	<code>luatexbase.new_chunkname(&lt;chunkname&gt;)</code>	Returns an allocation number for a Lua chunk name for use with <code>\directlua</code> and <code>\latelua</code> , indexed from 1. The number is returned and also <code>&lt;name&gt;</code> argument is added to the <code>lua.name</code> array at that index.
<code>new_luafunction</code>	<code>luatexbase.new_luafunction(&lt;functionname&gt;)</code>	

Returns an allocation number for a lua function for use with `\luafunction`, `\lateluafunction`, and `\luadef`, indexed from 1. The optional `<functionname>` argument is just used for logging.

These functions all require access to a named T<sub>E</sub>X count register to manage their allocations. The standard names are those defined above for access from T<sub>E</sub>X, e.g. `\e@alloc@attribute@count`, but these can be adjusted by defining the variable `<type>_count_name` before loading `ltluatex.lua`, for example

```
local attribute_count_name = "attributetracker"
require("ltluatex")
```

would use a T<sub>E</sub>X `\count` (`\countdef`'d token) called `attributetracker` in place of `\e@alloc@attribute@count`.

## 4.2 Lua access to T<sub>E</sub>X register numbers

`registernumber` `luatexbase.registernumber(<name>)`

Sometimes (notably in the case of Lua attributes) it is necessary to access a register *by number* that has been allocated by T<sub>E</sub>X. This package provides a function to look up the relevant number using LuaT<sub>E</sub>X's internal tables. After for example `\newattribute\myattrib, \myattrib` would be defined by (say) `\myattrib=\attribute15`. `luatexbase.registernumber("myattrib")` would then return the register number, 15 in this case. If the string passed as argument does not correspond to a token defined by `\attributedef`, `\countdef` or similar commands, the Lua value `false` is returned.

As an example, consider the input:

```
\newcommand\test[1]{%
\typeout{#1: \expandafter\meaning\csname#1\endcsname^^J
\space\space\space\space
\directlua{tex.write(luatexbase.registernumber("#1") or "bad input")}%
}}

\test{undefinedrubbish}

\test{space}

\test{hbox}

\test{@MM}

\test{@tempdima}
\test{@tempdimb}

\test{strutbox}

\test{sixt@@n}

\attributedef\myattr=12
\myattr=200
\test{myattr}
```

If the demonstration code is processed with Lua $\text{\LaTeX}$  then the following would be produced in the log and terminal output.

```
undefinedrubbish: \relax
      bad input
space: macro:->
      bad input
hbox: \hbox
      bad input
@MM: \mathchar"4E20
      20000
@tempdima: \dimen14
      14
@tempdimb: \dimen15
      15
strutbox: \char"B
      11
sist@@n: \char"10
      16
myattr: \attribute12
      12
```

Notice how undefined commands, or commands unrelated to registers do not produce an error, just return `false` and so print `bad input` here. Note also that commands defined by `\newbox` work and return the number of the box register even though the actual command holding this number is a `\chardef` defined token (there is no `\boxdef`).

### 4.3 Module utilities

`provides_module` `luatexbase.provides_module(<info>)`

This function is used by modules to identify themselves; the `info` should be a table containing information about the module. The required field `name` must contain the name of the module. It is recommended to provide a field `date` in the usual  $\text{\LaTeX}$  format `yyyy/mm/dd`. Optional fields `version` (a string) and `description` may be used if present. This information will be recorded in the log. Other fields are ignored. If the `version` begins with a digit, a `v` will be added at the start in the log.

`module_info` `luatexbase.module_info(<module>, <text>)`

`module_warning` `luatexbase.module_warning(<module>, <text>)`

`module_error` `luatexbase.module_error(<module>, <text>)`

These functions are similar to  $\text{\LaTeX}$ 's `\PackageError`, `\PackageWarning` and `\PackageInfo` in the way they format the output. No automatic line breaking is done, you may still use `\n` as usual for that, and the name of the package will be prepended to each output line.

Note that `luatexbase.module_error` raises an actual Lua error with `error()`, which currently means a call stack will be dumped. While this may not look pretty, at least it provides useful information for tracking the error down.

### 4.4 Callback management

`add_to_callback` `luatexbase.add_to_callback(<callback>, <function>, <description>)` Registers the *<function>* into the *<callback>* with a textual *<description>* of the function. Functions are inserted into the callback in the order loaded.

**remove\_from\_callback** `luatexbase.remove_from_callback(<callback>, <description>)` Removes the callback function with *<description>* from the *<callback>*. The removed function and its description are returned as the results of this function.

**in\_callback** `luatexbase.in_callback(<callback>, <description>)` Checks if the *<description>* matches one of the functions added to the list for the *<callback>*, returning a boolean value.

**disable\_callback** `luatexbase.disable_callback(<callback>)` Sets the *<callback>* to `false` as described in the LuaTeX manual for the underlying `callback.register` built-in. Callbacks will only be set to false (and thus be skipped entirely) if there are no functions registered using the callback.

**callback\_descriptions** A list of the descriptions of functions registered to the specified callback is returned. {} is returned if there are no functions registered.

**create\_callback** `luatexbase.create_callback(<name>, <type>, <default>)` Defines a user defined callback. The last argument is a default function or `false`.

**call\_callback** `luatexbase.call_callback(<name>, ...)` Calls a user defined callback with the supplied arguments.

**declare\_callback\_rule** `luatexbase.declare_callback_rule(<name>, <first>, <relation>, <second>)` Adds an ordering constraint between two callback functions for callback *<name>*.  
The kind of constraint added depends on *<relation>*:

**before** The callback function with description *<first>* will be executed before the function with description *<second>*.

**after** The callback function with description *<first>* will be executed after the function with description *<second>*.

**incompatible-warning** When both a callback function with description *<first>* and with description *<second>* is registered, then a warning is printed when the callback is executed.

**incompatible-error** When both a callback function with description *<first>* and with description *<second>* is registered, then an error is printed when the callback is executed.

**unrelated** Any previously declared callback rule between *<first>* and *<second>* gets disabled.

Every call to `declare_callback_rule` with a specific callback *<name>* and descriptions *<first>* and *<second>* overwrites all previous calls with same callback and descriptions.

The callback functions do not have to be registered yet when the functions is called. Only the constraints for which both callback descriptions refer to callbacks registered at the time the callback is called will have an effect.

## 5 Implementation

```

1 <*2ekernel | tex | latexrelease>
2 <2ekernel | latexrelease>\ifx\directlua\@undefined\else

```

### 5.1 Minimum LuaTeX version

LuaTeX has changed a lot over time. In the kernel support for ancient versions is not provided: trying to build a format with a very old binary therefore gives some information

in the log and loading stops. The cut-off selected here relates to the tree-searching behaviour of `require()`: from version 0.60, LuaTeX will correctly find Lua files in the `texmf` tree without ‘help’.

```

3 <latexrelease>\IncludeInRelease{2015/10/01}
4 <latexrelease>          {\newluafunction}{LuaTeX}%
5 \ifnum\luatexversion<60 %
6   \wlog{*****}
7   \wlog{* LuaTeX version too old for ltuatex support *}
8   \wlog{*****}
9   \expandafter\endinput
10 \fi

```

Two simple L<sup>A</sup>T<sub>E</sub>X macros from `ltdefns.dtx` have to be defined here because `ltdefns.dtx` is not loaded yet when `ltluatex.dtx` is executed.

```

11 \long\def\@gobble#1{}
12 \long\def\@firstofone#1{#1}

```

## 5.2 Older L<sup>A</sup>T<sub>E</sub>X/Plain T<sub>E</sub>X setup

```

13 <*tex>

```

Older L<sup>A</sup>T<sub>E</sub>X formats don’t have the primitives with ‘native’ names: sort that out. If they already exist this will still be safe.

```

14 \directlua{tex.enableprimitives("",tex.extraprimitives("luatex"))}
15 \ifx\@alloc\@undefined

```

In pre-2014 L<sup>A</sup>T<sub>E</sub>X, or plain T<sub>E</sub>X, load `etex.{sty,src}`.

```

16 \ifx\documentclass\@undefined
17   \ifx\loccount\@undefined
18     \input{etex.src}%
19   \fi
20   \catcode'\@=11 %
21   \outer\expandafter\def\csname newfam\endcsname
22     {\alloc@8\fam\chardef\et@xmaxfam}
23 \else
24   \RequirePackage{etex}
25   \expandafter\def\csname newfam\endcsname
26     {\alloc@8\fam\chardef\et@xmaxfam}
27   \expandafter\let\expandafter\new@mathgroup\csname newfam\endcsname
28 \fi

```

### 5.2.1 Fixes to `etex.src/etex.sty`

These could and probably should be made directly in an update to `etex.src` which already has some LuaTeX-specific code, but does not define the correct range for LuaTeX.

2015-07-13 higher range in `luatex`.

```

29 \edef \et@xmaxregs {\ifx\directlua\@undefined 32768\else 65536\fi}

```

`luatex/xetex` also allow more math fam.

```

30 \edef \et@xmaxfam {\ifx\Umathcode\@undefined\sixt@@n\else@cclvi\fi}
31 \count 270=\et@xmaxregs % locally allocates \count registers
32 \count 271=\et@xmaxregs % ditto for \dimen registers
33 \count 272=\et@xmaxregs % ditto for \skip registers
34 \count 273=\et@xmaxregs % ditto for \muskip registers
35 \count 274=\et@xmaxregs % ditto for \box registers

```

```

36 \count 275=\et@xmaxregs % ditto for \toks registers
37 \count 276=\et@xmaxregs % ditto for \marks classes
    and 256 or 16 fam. (Done above due to plain/LATEX differences in luatex.)
38 % \outer\def\newfam{\alloc@8\fam\chardef\et@xmaxfam}
    End of proposed changes to etex.src

```

### 5.2.2 luatex specific settings

Switch to global cf `luatex.sty` to leave room for inserts not really needed for `luatex` but possibly most compatible with existing use.

```

39 \expandafter\let\csname newcount\expandafter\expandafter\endcsname
40     \csname globcount\endcsname
41 \expandafter\let\csname newdimen\expandafter\expandafter\endcsname
42     \csname globdimen\endcsname
43 \expandafter\let\csname newskip\expandafter\expandafter\endcsname
44     \csname globskip\endcsname
45 \expandafter\let\csname newbox\expandafter\expandafter\endcsname
46     \csname globbox\endcsname

```

Define `\e@alloc` as in L<sup>A</sup>T<sub>E</sub>X (the existing macros in `etex.src` are hard to extend to further register types as they assume specific 26x and 27x count range). For compatibility the existing register allocation is not changed.

```

47 \chardef\e@alloc@top=65535
48 \let\e@alloc\chardef\chardef
49 \def\e@alloc#1#2#3#4#5#6{%
50     \global\advance#3\@ne
51     \e@ch@ck{#3}{#4}{#5}#1%
52     \allocationnumber#3\relax
53     \global#2#6\allocationnumber
54     \wlog{\string#6=\string#1\the\allocationnumber}}%
55 \gdef\e@ch@ck#1#2#3#4{%
56     \ifnum#1<#2\else
57         \ifnum#1=#2\relax
58             #1\@ccclvi
59             \ifx\count#4\advance#1 10 \fi
60         \fi
61         \ifnum#1<#3\relax
62         \else
63             \errmessage{No room for a new \string#4}%
64         \fi
65     \fi}%

```

Fix up allocations not to clash with `etex.src`.

```

66 \expandafter\csname newcount\endcsname\e@alloc@attribute@count
67 \expandafter\csname newcount\endcsname\e@alloc@ccodetable@count
68 \expandafter\csname newcount\endcsname\e@alloc@luafunction@count
69 \expandafter\csname newcount\endcsname\e@alloc@whatsit@count
70 \expandafter\csname newcount\endcsname\e@alloc@bytecode@count
71 \expandafter\csname newcount\endcsname\e@alloc@luachunk@count

```

End of conditional setup for plain T<sub>E</sub>X / old L<sup>A</sup>T<sub>E</sub>X.

```

72 \fi
73 </tex>

```

## 5.3 Attributes

`\newattribute` As is generally the case for the LuaTeX registers we start here from 1. Notably, some code assumes that `\attribute0` is never used so this is important in this case.

```

74 \ifx\@alloc@attribute@count\@undefined
75   \countdef\@alloc@attribute@count=258
76   \@alloc@attribute@count=\z@
77 \fi
78 \def\newattribute#1{%
79   \@alloc@attribute@attributedef
80   \@alloc@attribute@count\m@ne\@alloc@top#1%
81 }
```

*(End of definition for \newattribute.)*

`\setattribute` Handy utilities.

```

\unsetattribute 82 \def\setattribute#1#2{#1=\numexpr#2\relax}
83 \def\unsetattribute#1{#1=-"7FFFFFFF\relax}
```

*(End of definition for \setattribute and \unsetattribute.)*

## 5.4 Category code tables

`\newcatcodetable` Category code tables are allocated with a limit half of that used by LuaTeX for everything else. At the end of allocation there needs to be an initialization step. Table 0 is already taken (it's the global one for current use) so the allocation starts at 1.

```

84 \ifx\@alloc@ccodetable@count\@undefined
85   \countdef\@alloc@ccodetable@count=259
86   \@alloc@ccodetable@count=\z@
87 \fi
88 \def\newcatcodetable#1{%
89   \@alloc@catcodetable\chardef
90   \@alloc@ccodetable@count\m@ne{"8000}#1%
91   \initcatcodetable\allocationnumber
92 }
```

*(End of definition for \newcatcodetable.)*

`\catcodetable@initex` Save a small set of standard tables. The Unicode data is read here in using a parser simplified from that in `load-unicode-data`: only the nature of letters needs to be detected.

```

\catcodetable@string
\catcodetable@latex
\catcodetable@atletter
93 \newcatcodetable\catcodetable@initex
94 \newcatcodetable\catcodetable@string
95 \begingroup
96   \def\setrangecatcode#1#2#3{%
97     \ifnum#1>#2 %
98       \expandafter\@gobble
99     \else
100      \expandafter\@firstofone
101    \fi
102    {%
103      \catcode#1=#3 %
104      \expandafter\setrangecatcode\expandafter
105      {\number\numexpr#1 + 1\relax}{#2}{#3}
106    }%
```

```

107 }
108 \@firstofone{%

171 }
172 \endgroup

```

(End of definition for \catcodetable@initex and others.)

## 5.5 Named Lua functions

`\newluafunction` Much the same story for allocating LuaTeX functions except here they are just numbers so they are allocated in the same way as boxes. Lua indexes from 1 so once again slot 0 is skipped.

```

173 \ifx\e@alloc@luafunction@count\@undefined
174 \countdef\e@alloc@luafunction@count=260
175 \e@alloc@luafunction@count=\z@
176 \fi
177 \def\newluafunction{%
178 \e@alloc@luafunction\e@alloc@chardef
179 \e@alloc@luafunction@count\m@ne\e@alloc@top
180 }

```

(End of definition for \newluafunction.)

`\newluacmd` Additionally two variants are provided to make the passed control sequence call the function directly.

`\newprotectedluacmd`

```

181 \def\newluacmd{%
182 \e@alloc@luafunction\luadef
183 \e@alloc@luafunction@count\m@ne\e@alloc@top
184 }
185 \def\newprotectedluacmd{%
186 \e@alloc@luafunction{\protected\luadef}
187 \e@alloc@luafunction@count\m@ne\e@alloc@top
188 }

```

(End of definition for \newluacmd and \newprotectedluacmd.)

## 5.6 Custom whatsits

`\newwhatsit` These are only settable from Lua but for consistency are definable here.

```

189 \ifx\e@alloc@whatsit@count\@undefined
190 \countdef\e@alloc@whatsit@count=261
191 \e@alloc@whatsit@count=\z@
192 \fi
193 \def\newwhatsit#1{%
194 \e@alloc@whatsit\e@alloc@chardef
195 \e@alloc@whatsit@count\m@ne\e@alloc@top#1%
196 }

```

(End of definition for `\newwhatsit`.)

## 5.7 Lua bytecode registers

`\newluabytocode` These are only settable from Lua but for consistency are definable here.

```
197 \ifx\@alloc@bytecode@count\@undefined
198   \countdef\@alloc@bytecode@count=262
199   \@alloc@bytecode@count=\z@
200 \fi
201 \def\newluabytocode#1{%
202   \@alloc@luabytocode\@alloc@chardef
203   \@alloc@bytecode@count\m@ne\@alloc@top#1%
204 }
```

(End of definition for `\newluabytocode`.)

## 5.8 Lua chunk registers

`\newluachunkname` As for bytecode registers, but in addition we need to add a string to the `lua.name` table to use in stack tracing. We use the name of the command passed to the allocator, with no backslash.

```
205 \ifx\@alloc@luachunk@count\@undefined
206   \countdef\@alloc@luachunk@count=263
207   \@alloc@luachunk@count=\z@
208 \fi
209 \def\newluachunkname#1{%
210   \@alloc@luachunk\@alloc@chardef
211   \@alloc@luachunk@count\m@ne\@alloc@top#1%
212   {\escapechar\m@ne
213    \directlua{lua.name[\the\allocationnumber]="\string#1"}}%
214 }
```

(End of definition for `\newluachunkname`.)

## 5.9 Lua loader

Lua code loaded in the format often has to be loaded again at the beginning of every job, so we define a helper which allows us to avoid duplicated code:

```
215 \def\now@and@everyjob#1{%
216   \everyjob\expandafter{\the\everyjob
217     #1%
218   }%
219   #1%
220 }
```

Load the Lua code at the start of every job. For the conversion of  $\TeX$  into numbers at the Lua side we need some known registers: for convenience we use a set of systematic names, which means using a group around the Lua loader.

```
221 <2ekernel>\now@and@everyjob{%
222   \begingroup
223     \attributedef\attributezero=0 %
224     \chardef      \charzero      =0 %
```

Note name change required on older luatex, for hash table access.

```

225 \countdef \CountZero =0 %
226 \dimendef \dimenzero =0 %
227 \mathchardef \mathcharzero =0 %
228 \muskipdef \muskipzero =0 %
229 \skipdef \skipzero =0 %
230 \toksdef \tokszero =0 %
231 \directlua{require("ltnatex")}
232 \endgroup
233 <2ekernel>}

285 <2ekernel | latexrelease>\fi
286 </2ekernel | tex | latexrelease>

```

## 5.10 Lua module preliminaries

```

287 <*lua>

```

Some set up for the Lua module which is needed for all of the Lua functionality added here.

**luatexbase** Set up the table for the returned functions. This is used to expose all of the public functions.

```

288 luatexbase      = luatexbase or { }
289 local luatexbase = luatexbase

```

*(End of definition for luatexbase.)*

Some Lua best practice: use local versions of functions where possible.

```

290 local string_gsub      = string.gsub
291 local tex_count        = tex.count
292 local tex_setcount     = tex.setcount
293 local texio_write_nl   = texio.write_nl
294 local flush_list      = node.flush_list
295 local luatexbase_warning
296 local luatexbase_error

```

## 5.11 Lua module utilities

### 5.11.1 Module tracking

**modules** To allow tracking of module usage, a structure is provided to store information and to return it.

```

297 local modules = modules or { }

```

*(End of definition for modules.)*

**provides\_module** Local function to write to the log.

```

298 local function luatexbase_log(text)
299   texio_write_nl("log", text)
300 end

```

Modelled on `\ProvidesPackage`, we store much the same information but with a little more structure.

```

301 local function provides_module(info)
302   if not (info and info.name) then
303     luatexbase_error("Missing module name for provides_module")
304   end
305   local function spaced(text)
306     return text and (" " .. text) or ""
307   end
308   luatexbase_log(
309     "Lua module: " .. info.name
310     .. spaced(info.date)
311     .. spaced(info.version and string_gsub(info.version or "", "^(%d)", "v%1"))
312     .. spaced(info.description)
313   )
314   modules[info.name] = info
315 end
316 luatexbase.provides_module = provides_module

```

*(End of definition for provides\_module.)*

### 5.11.2 Module messages

There are various warnings and errors that need to be given. For warnings we can get exactly the same formatting as from `TEX`. For errors we have to make some changes. Here we give the text of the error in the `LATEX` format then force an error from Lua to halt the run. Splitting the message text is done using `\n` which takes the place of `\MessageBreak`.

First an auxiliary for the formatting: this measures up the message leader so we always get the correct indent.

```

317 local function msg_format(mod, msg_type, text)
318   local leader = ""
319   local cont
320   local first_head
321   if mod == "LaTeX" then
322     cont = string_gsub(leader, ".", " ")
323     first_head = leader .. "LaTeX: "
324   else
325     first_head = leader .. "Module " .. msg_type
326     cont = "(" .. mod .. ")"
327     .. string_gsub(first_head, ".", " ")
328     first_head = leader .. "Module " .. mod .. " " .. msg_type .. ":"
329   end
330   if msg_type == "Error" then
331     first_head = "\n" .. first_head
332   end
333   if string.sub(text, -1) ~= "\n" then
334     text = text .. " "
335   end
336   return first_head .. " "
337     .. string_gsub(
338       text
339       .. "on input line "

```

```

340         .. tex.inputlineno, "\n", "\n" .. cont .. " "
341     )
342     .. "\n"
343 end

module_info Write messages.
module_warning 344 local function module_info(mod, text)
module_error 345     texio_write_nl("log", msg_format(mod, "Info", text))
346 end
347 luatexbase.module_info = module_info
348 local function module_warning(mod, text)
349     texio_write_nl("term and log", msg_format(mod, "Warning", text))
350 end
351 luatexbase.module_warning = module_warning
352 local function module_error(mod, text)
353     error(msg_format(mod, "Error", text))
354 end
355 luatexbase.module_error = module_error

(End of definition for module_info, module_warning, and module_error.)
    Dedicated versions for the rest of the code here.

356 function luatexbase_warning(text)
357     module_warning("luatexbase", text)
358 end
359 function luatexbase_error(text)
360     module_error("luatexbase", text)
361 end

```

## 5.12 Accessing register numbers from Lua

Collect up the data from the T<sub>E</sub>X level into a Lua table: from version 0.80, LuaT<sub>E</sub>X makes that easy.

```

362 local luaregisterbasetable = { }
363 local registermap = {
364     attributezero = "assign_attr"    ,
365     charzero      = "char_given"     ,
366     CountZero     = "assign_int"     ,
367     dimenzero     = "assign_dimen"   ,
368     mathcharzero  = "math_given"     ,
369     muskipzero    = "assign_mu_skip" ,
370     skipzero      = "assign_skip"    ,
371     tokszero      = "assign_toks"    ,
372 }
373 local createtoken
374 if tex.luatexversion > 81 then
375     createtoken = token.create
376 elseif tex.luatexversion > 79 then
377     createtoken = newtoken.create
378 end
379 local hashtokens = tex.hashtokens()
380 local luatexversion = tex.luatexversion
381 for i,j in pairs (registermap) do
382     if luatexversion < 80 then

```

```

383     luaregisterbasetable[hashtokens[i][1]] =
384         hashtokens[i][2]
385     else
386         luaregisterbasetable[j] = createtoken(i).mode
387     end
388 end

```

**registernumber** Working out the correct return value can be done in two ways. For older LuaTeX releases it has to be extracted from the `hashtokens`. On the other hand, newer LuaTeX's have `newtoken`, and whilst `.mode` isn't currently documented, Hans Hagen pointed to this approach so we should be OK.

```

389 local registernumber
390 if luatexversion < 80 then
391     function registernumber(name)
392         local nt = hashtokens[name]
393         if(nt and luaregisterbasetable[nt[1]]) then
394             return nt[2] - luaregisterbasetable[nt[1]]
395         else
396             return false
397         end
398     end
399 else
400     function registernumber(name)
401         local nt = createtoken(name)
402         if(luaregisterbasetable[nt.cmdname]) then
403             return nt.mode - luaregisterbasetable[nt.cmdname]
404         else
405             return false
406         end
407     end
408 end
409 luatexbase.registernumber = registernumber

```

*(End of definition for registernumber.)*

## 5.13 Attribute allocation

**new\_attribute** As attributes are used for Lua manipulations its useful to be able to assign from this end.

```

410 local attributes=setmetatable(
411     {},
412     {
413         __index = function(t,key)
414             return registernumber(key) or nil
415         end}
416 )
417 luatexbase.attributes = attributes
418 local attribute_count_name =
419     attribute_count_name or "e@alloc@attribute@count"
420 local function new_attribute(name)
421     tex_setcount("global", attribute_count_name,
422                 tex_count[attribute_count_name] + 1)
423     if tex_count[attribute_count_name] > 65534 then
424         luatexbase_error("No room for a new \\attribute")

```

```

425     end
426     attributes[name]= tex_count[attribute_count_name]
427     luatexbase_log("Lua-only attribute " .. name .. " = " ..
428                   tex_count[attribute_count_name])
429     return tex_count[attribute_count_name]
430 end
431 luatexbase.new_attribute = new_attribute

```

*(End of definition for new\_attribute.)*

## 5.14 Custom whatsit allocation

**new\_whatsit** Much the same as for attribute allocation in Lua.

```

432 local whatsit_count_name = whatsit_count_name or "e@alloc@whatsit@count"
433 local function new_whatsit(name)
434     tex_setcount("global", whatsit_count_name,
435                 tex_count[whatsit_count_name] + 1)
436     if tex_count[whatsit_count_name] > 65534 then
437         luatexbase_error("No room for a new custom whatsit")
438     end
439     luatexbase_log("Custom whatsit " .. (name or "") .. " = " ..
440                 tex_count[whatsit_count_name])
441     return tex_count[whatsit_count_name]
442 end
443 luatexbase.new_whatsit = new_whatsit

```

*(End of definition for new\_whatsit.)*

## 5.15 Bytecode register allocation

**new\_bytecode** Much the same as for attribute allocation in Lua. The optional *<name>* argument is used in the log if given.

```

444 local bytecode_count_name =
445     bytecode_count_name or "e@alloc@bytecode@count"
446 local function new_bytecode(name)
447     tex_setcount("global", bytecode_count_name,
448                 tex_count[bytecode_count_name] + 1)
449     if tex_count[bytecode_count_name] > 65534 then
450         luatexbase_error("No room for a new bytecode register")
451     end
452     luatexbase_log("Lua bytecode " .. (name or "") .. " = " ..
453                 tex_count[bytecode_count_name])
454     return tex_count[bytecode_count_name]
455 end
456 luatexbase.new_bytecode = new_bytecode

```

*(End of definition for new\_bytecode.)*

## 5.16 Lua chunk name allocation

**new\_chunkname** As for bytecode registers but also store the name in the lua.name table.

```

457 local chunkname_count_name =
458     chunkname_count_name or "e@alloc@luachunk@count"
459 local function new_chunkname(name)

```

```

460 tex_setcount("global", chunkname_count_name,
461             tex_count[chunkname_count_name] + 1)
462 local chunkname_count = tex_count[chunkname_count_name]
463 chunkname_count = chunkname_count + 1
464 if chunkname_count > 65534 then
465     luatexbase_error("No room for a new chunkname")
466 end
467 lua.name[chunkname_count]=name
468 luatexbase_log("Lua chunkname " .. (name or "") .. " = " ..
469             chunkname_count .. "\n")
470 return chunkname_count
471 end
472 luatexbase.new_chunkname = new_chunkname

```

*(End of definition for new\_chunkname.)*

## 5.17 Lua function allocation

**new\_luafunction** Much the same as for attribute allocation in Lua. The optional *<name>* argument is used in the log if given.

```

473 local luafunction_count_name =
474             luafunction_count_name or "e@alloc@luafunction@count"
475 local function new_luafunction(name)
476     tex_setcount("global", luafunction_count_name,
477             math.max(
478                 #(lua.get_functions_table()),
479                 tex_count[luafunction_count_name])
480             + 1)
481     lua.get_functions_table()[tex_count[luafunction_count_name]] = false
482     if tex_count[luafunction_count_name] > 65534 then
483         luatexbase_error("No room for a new luafunction register")
484     end
485     luatexbase_log("Lua function " .. (name or "") .. " = " ..
486             tex_count[luafunction_count_name])
487     return tex_count[luafunction_count_name]
488 end
489 luatexbase.new_luafunction = new_luafunction

```

*(End of definition for new\_luafunction.)*

## 5.18 Lua callback management

The native mechanism for callbacks in LuaTeX allows only one per function. That is extremely restrictive and so a mechanism is needed to add and remove callbacks from the appropriate hooks.

### 5.18.1 Housekeeping

The main table: keys are callback names, and values are the associated lists of functions. More precisely, the entries in the list are tables holding the actual function as **func** and the identifying description as **description**. Only callbacks with a non-empty list of functions have an entry in this list.

Actually there are two tables: `realcallbacklist` directly contains the entries as described above while `callbacklist` only directly contains the already sorted entries. Other entries can be queried through `callbacklist` too which triggers a resort.

Additionally `callbackrules` describes the ordering constraints: It contains two element tables with the descriptions of the constrained callback implementations. It can additionally contain a `type` entry indicating the kind of rule. A missing value indicates a normal ordering constraint.

```

490 local realcallbacklist = {}
491 local callbackrules = {}
492 local callbacklist = setmetatable({}, {
493   __index = function(t, name)
494     local list = realcallbacklist[name]
495     local rules = callbackrules[name]
496     if list and rules then
497       local meta = {}
498       for i, entry in ipairs(list) do
499         local t = {value = entry, count = 0, pos = i}
500         meta[entry.description], list[i] = t, t
501       end
502       local count = #list
503       local pos = count
504       for i, rule in ipairs(rules) do
505         local rule = rules[i]
506         local pre, post = meta[rule[1]], meta[rule[2]]
507         if pre and post then
508           if rule.type then
509             if not rule.hidden then
510               assert(rule.type == 'incompatible-warning' and luatexbase_warning
511                 or rule.type == 'incompatible-error' and luatexbase_error)(
512                 "Incompatible functions \"" .. rule[1] .. "\" and \"" .. rule[2]
513                 .. "\" specified for callback \"" .. name .. "\".")
514               rule.hidden = true
515             end
516           else
517             local post_count = post.count
518             post.count = post_count+1
519             if post_count == 0 then
520               local post_pos = post.pos
521               if post_pos ~= pos then
522                 local new_post_pos = list[pos]
523                 new_post_pos.pos = post_pos
524                 list[post_pos] = new_post_pos
525               end
526               list[pos] = nil
527               pos = pos - 1
528             end
529             pre[#pre+1] = post
530           end
531         end
532       end
533       for i=1, count do -- The actual sort begins
534         local current = list[i]
535         if current then

```

```

536     meta[current.value.description] = nil
537   for j, cur in ipairs(current) do
538     local count = cur.count
539     if count == 1 then
540       pos = pos + 1
541       list[pos] = cur
542     else
543       cur.count = count - 1
544     end
545   end
546   list[i] = current.value
547 else
548   -- Cycle occurred. TODO: Show cycle for debugging
549   -- list[i] = ...
550   local remaining = {}
551   for name, entry in next, meta do

555   end
556   table.sort(remaining)
557   local first_name = remaining[1]
558   for j, name in ipairs(remaining) do
559     local entry = meta[name]
560     list[i + j - 1] = entry.value
561     for _, post_entry in ipairs(entry) do
562       local post_name = post_entry.value.description
563       if not remaining[post_name] then
564         remaining[post_name] = name
565       end
566     end
567   end
568   local cycle = {first_name}
569   local index = 1
570   local last_name = first_name
571   repeat
572     cycle[last_name] = index
573     last_name = remaining[last_name]
574     index = index + 1
575     cycle[index] = last_name
576   until cycle[last_name]
577   local length = index - cycle[last_name] + 1
578   table.move(cycle, cycle[last_name], index, 1)
579   for i=2, length//2 do
580     cycle[i], cycle[length + 1 - i] = cycle[length + 1 - i], cycle[i]
581   end
582   error('Cycle occurred at ' .. table.concat(cycle, ' -> ', 1, length))
583 end
584 end
585 end
586 realcallbacklist[name] = list
587 t[name] = list
588 return list
589 end

```

```
590 })
```

Numerical codes for callback types, and name-to-value association (the table keys are strings, the values are numbers).

```
591 local list, data, exclusive, simple, reverselist = 1, 2, 3, 4, 5
592 local types = {
593   list      = list,
594   data      = data,
595   exclusive = exclusive,
596   simple    = simple,
597   reverselist = reverselist,
598 }
```

Now, list all predefined callbacks with their current type, based on the LuaTeX manual version 1.01. A full list of the currently-available callbacks can be obtained using

```
\directlua{
  for i,_ in pairs(callback.list()) do
    texio.write_nl("- " .. i)
  end
}
\bye
```

in plain LuaTeX. (Some undocumented callbacks are omitted as they are to be removed.)

```
599 local callbacktypes = callbacktypes or {
```

Section 8.2: file discovery callbacks.

```
600   find_read_file      = exclusive,

675 }
676 luatexbase.callbacktypes=callbacktypes

```

Sometimes multiple callbacks correspond to a single underlying engine level callback. Then the engine level callback should be registered as long as at least one of these callbacks is in use. This is implemented though a shared table which counts how many of the involved callbacks are currently in use. The engine level callback is registered iff this count is not 0.

We add `mlist_to_hlist` directly to the list to demonstrate this, but the handler gets added later when it is actually defined.

All callbacks in this list are treated as user defined callbacks.

```

677 local shared_callbacks = {
678   mlist_to_hlist = {
679     callback = "mlist_to_hlist",
680     count = 0,
681     handler = nil,
682   },
683 }
684 shared_callbacks.pre_mlist_to_hlist_filter = shared_callbacks.mlist_to_hlist
685 shared_callbacks.post_mlist_to_hlist_filter = shared_callbacks.mlist_to_hlist

```

`callback.register` Save the original function for registering callbacks and prevent the original being used. The original is saved in a place that remains available so other more sophisticated code can override the approach taken by the kernel if desired.

```

686 local callback_register = callback_register or callback.register
687 function callback.register()
688   luatexbase_error("Attempt to use callback.register() directly\n")
689 end

```

*(End of definition for `callback.register`.)*

### 5.18.2 Handlers

The handler function is registered into the callback when the first function is added to this callback's list. Then, when the callback is called, the handler takes care of running all functions in the list. When the last function is removed from the callback's list, the handler is unregistered.

More precisely, the functions below are used to generate a specialized function (closure) for a given callback, which is the actual handler.

The way the functions are combined together depends on the type of the callback. There are currently 4 types of callback, depending on the calling convention of the functions the callback can hold:

**simple** is for functions that don't return anything: they are called in order, all with the same argument;

**data** is for functions receiving a piece of data of any type except node list head (and possibly other arguments) and returning it (possibly modified): the functions are called in order, and each is passed the return value of the previous (and the other arguments untouched, if any). The return value is that of the last function;

**list** is a specialized variant of *data* for functions filtering node lists. Such functions are called with a node list head as the first argument and may return either the head of a modified node list, or the boolean values **true** or **false**. The functions are chained the same way as for *data* except for the following cases. If a function returns **false**, then **false** is immediately returned and the following functions are *not* called. If a function returns **true**, then the same head is passed to the next function. If all functions return **true**, then the original head is returned, otherwise the return value of the last function not returning **true** is used.

**reverselist** is a specialized variant of *list* which executes functions in inverse order.

**exclusive** is for functions with more complex signatures; functions in this type of callback are *not* combined: An error is raised if a second callback is registered.

Handler for **data** callbacks.

```

690 local function data_handler(name)
691   return function(data, ...)
692     for _,i in ipairs(callbacklist[name]) do
693       data = i.func(data,...)
694     end
695     return data
696   end
697 end

```

Default for user-defined **data** callbacks without explicit default.

```

698 local function data_handler_default(value)
699   return value
700 end

```

Handler for **exclusive** callbacks. We can assume `callbacklist[name]` is not empty: otherwise, the function wouldn't be registered in the callback any more.

```

701 local function exclusive_handler(name)
702   return function(...)
703     return callbacklist[name][1].func(...)
704   end
705 end

```

Handler for **list** callbacks.

```

706 local function list_handler(name)
707   return function(head, ...)
708     local ret
709     for _,i in ipairs(callbacklist[name]) do
710       ret = i.func(head, ...)
711       if ret == false then
712         luatexbase_warning(
713           "Function '" .. i.description .. "' returned false\n"
714           .. "in callback '" .. name .. "'")
715       )
716       return false
717     end

```

```

718     if ret ~= true then
719         head = ret
720     end
721 end
722 return head
723 end
724 end

```

Default for user-defined `list` and `reverselist` callbacks without explicit default.

```

725 local function list_handler_default(head)
726 return head
727 end

```

Handler for `reverselist` callbacks.

```

728 local function reverselist_handler(name)
729 return function(head, ...)
730     local ret
731     local callbacks = callbacklist[name]
732     for i = #callbacks, 1, -1 do
733         local cb = callbacks[i]
734         ret = cb.func(head, ...)
735         if ret == false then
736             luatexbase_warning(
737                 "Function '" .. cb.description .. "' returned false\n"
738                 .. "in callback '" .. name .. "'")
739         )
740         return false
741     end
742     if ret ~= true then
743         head = ret
744     end
745 end
746 return head
747 end
748 end

```

Handler for `simple` callbacks.

```

749 local function simple_handler(name)
750 return function(...)
751     for _,i in ipairs(callbacklist[name]) do
752         i.func(...)
753     end
754 end
755 end

```

Default for user-defined `simple` callbacks without explicit default.

```

756 local function simple_handler_default()
757 end

```

Keep a handlers table for indexed access and a table with the corresponding default functions.

```

758 local handlers = {
759     [data] = data_handler,
760     [exclusive] = exclusive_handler,
761     [list] = list_handler,
762     [reverselist] = reverselist_handler,

```

```

763 [simple]      = simple_handler,
764 }
765 local defaults = {
766 [data]       = data_handler_default,
767 [exclusive]  = nil,
768 [list]       = list_handler_default,
769 [reverselist] = list_handler_default,
770 [simple]      = simple_handler_default,
771 }

```

### 5.18.3 Public functions for callback management

Defining user callbacks perhaps should be in package code, but impacts on `add_to_callback`. If a default function is not required, it may be declared as `false`. First we need a list of user callbacks.

```

772 local user_callbacks_defaults = {}

```

`create_callback` The allocator itself.

```

773 local function create_callback(name, ctype, default)
774   local ctype_id = types[ctype]
775   if not name or name == ""
776   or not ctype_id
777   then
778     luatexbase_error("Unable to create callback:\n" ..
779                       "valid callback name and type required")
780   end
781   if callbacktypes[name] then
782     luatexbase_error("Unable to create callback '" .. name ..
783                       "':\ncallback is already defined")

# File 05

## ltxexpl.dtx

### 1 expl3-dependent code

#### 1.1 Loader

```
\@kernel@after@enddocument
\@kernel@before@enddocument@afterlastpage
\@kernel@after@enddocument@afterlastpage
```

These three kernel hooks are used by the shipout code. They are defined early (i.e., here) because the lthooks code adds material to them.

```
1 <*2ekernel | latexrelease>
2 <latexrelease> \IncludeInRelease{2020/10/01}%
3 <latexrelease> {kernel@enddocument hooks}{Define several kernel hooks}
```

We initialize these kernel hooks only when they do not already exist. Otherwise they would be set to \@empty on rollback, which would be wrong because code that has been added to them may still have to be executed in the rollback situation. Instead code that writes to them needs to handle the rollback as needed. It is likely that we have to change that approach in the future, but for now it should do. (It is enough to test only for the existence of one hook, as all got added at the same time.)

```
4 \ifx\@kernel@after@enddocument\undefined
5   \let \@kernel@after@enddocument \@empty
6   \let \@kernel@after@enddocument@afterlastpage \@empty
```

For the similar reasons we also define those that are used in \document because they too get material added to in early modules.

```
\@kernel@before@begindocument
\@kernel@after@begindocument
```

```
7   \let \@kernel@before@begindocument \@empty
8   \let \@kernel@after@begindocument \@empty
9 \fi
```

This one actually came later so we need to have a separate check, but otherwise we don't bother with a separate rollback.

```
10 \ifx\@kernel@before@enddocument@afterlastpage\undefined
11   \let \@kernel@before@enddocument@afterlastpage \@empty
12 \fi
13 <latexrelease> \EndIncludeInRelease
14 <latexrelease> \IncludeInRelease{0000/00/00}%
15 <latexrelease> {kernel@enddocument hooks}{Define several kernel hooks}
16 <latexrelease> \let\@kernel@after@enddocument\undefined
17 <latexrelease> \let\@kernel@before@enddocument@afterlastpage\undefined
18 <latexrelease> \let\@kernel@after@enddocument@afterlastpage\undefined
19 <latexrelease> \let\@kernel@before@begindocument\undefined
20 <latexrelease> \let\@kernel@after@begindocument\undefined
21 </2ekernel | latexrelease>
22 <latexrelease> \EndIncludeInRelease
```

(End of definition for \@kernel@after@enddocument and others.)

First define some blank commands, so that in case something goes wrong while loading expl3, we won't get strange Undefined control sequence errors.

```

129 <latexrelease>  }
130 <latexrelease>  {%
131 <latexrelease>    \message{Skipping expl3-dependent extensions}%
132 <latexrelease>    \@gobbletwo
133 <latexrelease>  }%
134 <latexrelease>\input{expl3.ltx}
135 <latexrelease>\EndIncludeInRelease

```

Now in `latexrelease` mode, redefine a few commands to avoid “already defined” errors.

```

136 <latexrelease>\@ifundefined{ExplSyntaxOff}{\{\}\latexrelease@postltxpl}

```

## 1.2 Using expl3 code

In order to ease the implementation of some new features in L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> we may (temporarily) use some coding based on the `expl3`-code. Such macros will eventually vanish and may be changed unannounced. They are there for internal use in the L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> kernel and are not meant to be used in third-party packages. These macros will always have the `@expl@` prefix in their name.

The rest of the name matches the `expl3` name but with all underscores replaced by `@s` and the `:` replaced by `@@`, e.g.,

```
\cs_new_eq:NN \@expl@tl@trim@spaces@apply@@nN \tl_trim_spaces_apply:nN
```

if that `expl3` command is needed in places that are others coded in L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> conventions.

In this file, each release of LaTeX adds an `\IncludeInRelease` block, in which the macros copied for that release were defined. In case a rollback is requested, the entire block is changed.

Each macro copied has a `\changes` entry to explain when and why it was copied, so that further to that may spot it easily.

Here `\cs_gset_eq:NN` is used, instead of the `new` variant because if different releases use that same name for different purposes, each can copy the macro without worrying about redefinitions.

```

137 <latexrelease>\IncludeInRelease{2020/10/01}{\@expl@cs@to@str@@N}%
138 <latexrelease>          {expl3 macros added for the 2020-10-01 release}%

```

The expl3 activation needs to be inside the release guards as otherwise rolling forward is broken in old kernels that do not have expl3 loaded.

```

139 \ExplSyntaxOn

140 \cs_gset_eq:NN \@expl@cs@to@str@{N} \cs_to_str:N
141 \cs_gset_eq:NN \@expl@str@if@eq@{nnTF} \str_if_eq:nnTF

142 \cs_gset_eq:NN \@expl@cs@prefix@spec@{N} \cs_prefix_spec:N
143 \cs_if_exist:NTF \cs_parameter_spec:N
144 { \cs_gset_eq:NN \@expl@cs@parameter@spec@{N} \cs_parameter_spec:N }
145 { \cs_gset_eq:NN \@expl@cs@parameter@spec@{N} \cs_argument_spec:N }
146 \cs_gset_eq:NN \__kernel_cs_parameter_spec:N \@expl@cs@parameter@spec@{N}
147 \cs_gset_eq:NN \@expl@cs@replacement@spec@{N} \cs_replacement_spec:N

148 \cs_gset_eq:NN \@expl@str@map@function@{NN} \str_map_function:NN
149 \cs_gset_eq:NN \@expl@char@generate@{nn} \char_generate:nn

150 \ExplSyntaxOff

```

Here we can't assume that expl3 is available. It will be if we roll back but if this code is executed rolling forward it needs to be pure 2e.

```

151 \<latexrelease>\EndIncludeInRelease
152 \<latexrelease>\IncludeInRelease{0000/00/00}{\@expl@cs@to@str@{N}}%

160 \<latexrelease>\EndIncludeInRelease
161 \</2ekernel|latexrelease>

```

## 2 Document-level command names for expl3 functions

Current home for L3 programming layer functions that we make directly available at the document level. This section may need to be moved later (after `\NewDocumentCommand` is defined in case we want to use that in the setup).

`\fpeval` The expandable command `\fpeval` takes as its argument a floating point expression and produces a result using the normal rules of mathematics. As this command is expandable it can be used where T<sub>E</sub>X requires a number and for example within a low-level `\edef` operation to give a purely numerical result. See `usrguide3` for further explanation.

`\inteval` The expandable command `\inteval` takes as its argument an integer expression and produces a result using the normal rules of mathematics. The operations recognised are `\dimeval` `\skipeval` `+`, `-`, `*` and `/` plus parentheses. Division occurs with *rounding*, and ties are rounded away from zero. As this command is expandable it can be used where T<sub>E</sub>X requires a number and for example within a low-level `\edef` operation to give a purely numerical result. See `usrguide3` for further explanation. `\dimeval` and `\skipeval` are similar, but generate fixed and rubber length values, respectively.

`\fpeval` A document level wrapper around the code level function for floating point calculations.

`\interval`

`\dimeval` 162 `<*2ekernel | latexrelease>`

`\skipeval` 163 `<latexrelease>\IncludeInRelease{2022/06/01}%`  
164 `<latexrelease> {\fpeval}{fp and int calculations}%`  
165 `\ExplSyntaxOn`  
166 `\cs_new_eq:NN \fpeval \fp_eval:n`

And a few more, this time wrappers around the eTeX primitives.

167 `\cs_new_eq:NN \interval \int_eval:n`

168 `\cs_new_eq:NN \dimeval \dim_eval:n`  
169 `\cs_new_eq:NN \skipeval \skip_eval:n`  
170 `\ExplSyntaxOff`

*(End of definition for \fpeval and others.)*

171 `</2ekernel | latexrelease>`  
172 `<latexrelease>\EndIncludeInRelease`  
173 `<latexrelease>\IncludeInRelease{0000/00/00}%`  
174 `<latexrelease> {\fpeval}{fp and int calculations}%`  
175 `<latexrelease>`  
176 `<latexrelease>\let\fpeval\@undefined`  
177 `<latexrelease>\let\interval\@undefined`  
178 `<latexrelease>\let\dimeval\@undefined`  
179 `<latexrelease>\let\skipeval\@undefined`  
180 `<latexrelease>\EndIncludeInRelease`

`\UseName` When declaring new commands with `\NewDocumentCommand` or `\NewCommandCopy`

`\ExpandArgs` or similar, it is sometimes necessary to “construct” the csname. As a general mechanism the L3 programming layer has `\exp_args:N...` for this, but there is no mechanism for it if `\ExplSyntaxOn` is not active. We therefore offer a few of these commands also with CamelCase names.

`\UseName` A document wrapper for changing arguments to cs names for use with `\NewDocumentCommand`

`\ExpandArgs` and similar functions.

181 `<*2ekernel | latexrelease>`  
182 `<latexrelease>\IncludeInRelease{2022/06/01}%`  
183 `<latexrelease> {\ExpandArgs}{Some pre-expansion commands}%`  
184 `\ExplSyntaxOn`  
185 `\cs_new_eq:NN \UseName \use:c`

186 `\cs_new:Npn \ExpandArgs #1`  
187 `{`  
188 `\cs_if_exist_use:cF { exp_args:N #1 }`  
189 `{ \msg_expandable_error:nnn { kernel } { unknown-arg-expansion } {#1} }`  
190 `}`  
191 `\msg_new:nnn { kernel } { unknown-arg-expansion }`  
192 `{ Unknown-arg-expansion-“#1” }`  
193 `\ExplSyntaxOff`

*(End of definition for \UseName and \ExpandArgs.)*

194 `</2ekernel | latexrelease>`  
195 `<latexrelease>\EndIncludeInRelease`  
196 `<latexrelease>\IncludeInRelease{0000/00/00}%`  
197 `<latexrelease> {\ExpandArgs}{Some pre-expansion commands}%`

```

198 <latexrelease>
199 <latexrelease>\let\UserName\@undefined
200 <latexrelease>\let\ExpandArgs\@undefined
201 <latexrelease>\EndIncludeInRelease

\IfExplAtLeastTF      A pretty simple set of wrappers. \IfExplAtLeastTF was already introduced in 2023
\IfExplAtLeastT      but since we pretend that these commands were always there, even in rollback, things
\IfExplAtLeastF      can be kept simple and we just alter the rollback date.

\IfExplAtLeastTF

202 <*2ekernel | latexrelease>
203 <latexrelease>\IncludeInRelease{2025/06/01}%
204 <latexrelease>          {\IfExplAtLeastTF}{Test for expl3 date}%

# File 06

## ltdefns.dtx

### 1 Definitions

This section contains commands used in defining other macros.

```
1 <*2ekernel>
```

#### 1.1 Initex initializations

`\two@digits` Prefix a number less than 10 with ‘0’.

```
2 \def\two@digits#1{\ifnum#1<10 0\fi\number#1}
```

*(End of definition for \two@digits.)*

`\typeout` Display something on the terminal.

```
3 </2ekernel>
4 <*2ekernel | latexrelease>
5 <latexrelease> \IncludeInRelease{2020/10/01}%
6 <latexrelease> { \typeout}{Allow "par" in \typeout}%
7 \protected\long\def\typeout#1{\begingroup
8   \set@display@protect
9   \def\par{^^J^^J}%
10  \immediate\write\@unused{#1}\endgroup}
11 </2ekernel | latexrelease>
12 <latexrelease> \EndIncludeInRelease
13 <latexrelease> \IncludeInRelease{0000/00/00}%
14 <latexrelease> { \typeout}{Allow "par" in \typeout}%
15 <latexrelease>
16 <latexrelease> \def\typeout#1{\begingroup\set@display@protect
17 <latexrelease> \immediate\write\@unused{#1}\endgroup}
18 <latexrelease> \EndIncludeInRelease
19 <*2ekernel>
```

*(End of definition for \typeout.)*

`\newlinechar` A char to be used as new-line in output to files.

```
20 \newlinechar‘^^J
```

*(End of definition for \newlinechar.)*

#### 1.2 Saved versions of TeX primitives

The TeX primitive `\foo` is saved as `\@@foo`. The following primitives are handled in this way:

`\@@par`

```
21 \let\@@par=\par
22 %\let\@@input=\input      %%% moved earlier
23 %\let\@@end=\end          %%%
```

*(End of definition for \@@par.)*

`\@@hyph` Save original primitive definition.

```

24 \let\@@hyph=\-

```

(End of definition for `\@@hyph`.)

`\@@italiccorr` Save the original italic correction.

```

25 \let\@@italiccorr=\/

```

(End of definition for `\@@italiccorr`.)

`\@height` The following definitions save token space. E.g., using `\@height` instead of `height` saves

`\@depth` 5 tokens at the cost in time of one macro expansion.

```

\@width 26 \def\@height{height} \def\@depth{depth} \def\@width{width}
\@minus 27 \def\@minus{minus}
\@plus 28 \def\@plus{plus}

```

The next one is another 100 tokens worth.

```

29 \def\hb@xt@{\hbox to}

```

(End of definition for `\@height` and others.)

```

30 \message{hacks,}

```

`\hb@xt@`

### 1.3 Command definitions

This section defines the following commands:

`\@namedef` `{\NAME}`  
Expands to `\def\NAME`, except name can contain any characters.

`\@nameuse` `{\NAME}`  
Expands to `\NAME`.

`\@ifnextchar` `X{\YES}{\NO}`  
Expands to `\YES` if next character is an ‘X’, and to `\NO` otherwise. (Uses `\reserved@a-`  
`\reserved@c`.) NOTE: GOBBLES ANY SPACE FOLLOWING IT.

`\@ifstar` `{\YES}{\NO}`  
Gobbles following spaces and then tests if next the character is a ‘\*’. If it is, then it  
gobbles the ‘\*’ and expands to `\YES`, otherwise it expands to `\NO`.

`\@dblarg` `{\CMD}{\ARG}`  
Expands to `\{\CMD\}[\ARG]{\ARG}`. Use `\@dblarg\CS` when `\CS` takes arguments  
`[ARG1]{ARG2}`, where default is `ARG1 = ARG2`.

`\@ifundefined` `{\NAME}{\YES}{\NO}`  
: If `\NAME` is undefined then it executes `\YES`, otherwise it executes `\NO`. More precisely,  
true if `\NAME` either undefined or = `\relax`.

`\@ifdefinable` `\NAME{\YES}` Executes `\YES` if the user is allowed to define `\NAME`, otherwise it  
gives an error. The user can define `\NAME` if `\@ifundefined{\NAME}` is true, ‘`NAME`’ ≠  
‘`relax`’ and the first three letters of ‘`NAME`’ are not ‘`end`’, and if `\endNAME` is not defined.

`\newcommand` `*{\FOO}[\i]{\TEXT}`  
User command to define `\FOO` to be a macro with `i` arguments (`i = 0` if missing) having  
the definition `\TEXT`. Produces an error if `\FOO` already defined.

Normally the command is defined to be `\long` (ie it may take multiple paragraphs  
in its argument). In the star-form, the command is not defined as `\long` and a blank line  
in any argument to the command would generate an error.

`\renewcommand` `*{\FOO}[\i]{\TEXT}`

Same as `\newcommand`, except it checks if `\F00` already defined.

`\newenvironment`       $\star\{\langle FOO\rangle\}[\langle i\rangle]\{\langle DEF1\rangle\}\{\langle DEF2\rangle\}$   
equivalent to:  
`\newcommand{\F00}[i]{DEF1} \def{\endF00}{DEF2}`  
(or the appropriate star forms).

`\renewenvironment`      Obvious companion to `\newenvironment`.

`\@cons`                : See description of `\output` routine.

`\@car`                `\@car T1 T2 ... Tn\@nil == T1` (unexpanded)

`\@cdr`                `\@cdr T1 T2 ... Tn\@nil == T2 ... Tn` (unexpanded)

`\typeout`              $\{\langle message\rangle\}$   
Produces a warning message on the terminal.

`\typein`              $\{\langle message\rangle\}$   
Types message, asks the user to type in a command, then executes it

`\typein`              $[\langle\backslash CS\rangle]\{\langle MSG\rangle\}$   
Same as above, except defines `\CS` to be the input instead of executing it.

`\typein`

```

31 \def\typein{%
32   \let\@typein\relax
33   \@testopt\@xtypein\@typein}

34 \ifx\directlua\@undefined

35 \def\@xtypein[#1]#2{%
36   \typeout{#2}%
37   \advance\endlinechar\@M
38   \read\@inputcheck to#1%
39   \advance\endlinechar-\@M
40   \@typein}%

41 \else

42 \def\@xtypein[#1]#2{%
43   \typeout{#2}%
44   \begingroup \endlinechar\m@ne
45   \read\@inputcheck to#1%
46   \expandafter\endgroup
47   \expandafter\def\expandafter#1\expandafter{#1}%
48   \@typein}%

49 \fi

```

(End of definition for `\typein`.)

`\@namedef`

```

50 \def\@namedef#1{\expandafter\def\csname #1\endcsname}

```

(End of definition for `\@namedef`.)

`\@nameuse`

```

51 \def\@nameuse#1{\csname #1\endcsname}

```

(End of definition for `\@nameuse`.)

```

\@cons
52 \def\@cons#1#2{\begingroup\let\@elt\relax\xdef#1{#1\@elt #2}\endgroup}

(End of definition for \@cons.)

\@car
\@cdr
53 \def\@car#1#2\@nil{#1}
54 \def\@cdr#1#2\@nil{#2}

(End of definition for \@car and \@cdr.)

\@carcube \@carcube T1 ... Tn\@nil = T1 T2 T3 ,  $n > 3$ 
55 \</2ekernel>
56 \<latexrelease>\IncludeInRelease{2020/10/01}{\@carcube}{Make \@carcube long}%
57 \<*2ekernel | latexrelease>
58 \long\def\@carcube#1#2#3#4\@nil{#1#2#3}
59 \</2ekernel | latexrelease>
60 \<latexrelease>\EndIncludeInRelease
61 %
62 \<latexrelease>\IncludeInRelease{0000/00/00}{\@carcube}{Undo: Make \@carcube long}%
63 \<latexrelease>\def\@carcube#1#2#3#4\@nil{#1#2#3}
64 \<latexrelease>\EndIncludeInRelease
65 \<*2ekernel>

(End of definition for \@carcube.)

\@onlypreamble This macro adds its argument to the list of commands stored in \@preamblecmds
\@preamblecmds to be disabled after \begin{document}. These commands are redefined to generate
\@notprerr at this point.
66 \def\@preamblecmds{}
67 \def\@onlypreamble#1{%
68   \expandafter\gdef\expandafter\@preamblecmds\expandafter{%
69     \@preamblecmds\do#1}}
70 \@onlypreamble\@onlypreamble
71 \@onlypreamble\@preamblecmds

(End of definition for \@onlypreamble and \@preamblecmds.)

\@star@or@long Look ahead for a *. If present reset \l@ngrel@x so that the next definition, #1, will be
non-long.
72 \</2ekernel>
73 \<*2ekernel | latexrelease>
74 \<latexrelease>\IncludeInRelease{2025/11/01}%
75 \<latexrelease> {\@star@or@long}{Macros without args are short}%
76 \def\@star@or@long#1{%

By default commands defined with \newcommand and friends are not \protected so
\pr@tectedrel@x is set to \relax.
77 \let\pr@tectedrel@x\relax
78 \@ifstar
79 {\let\l@ngrel@x\relax#1}%
80 {\let\l@ngrel@x\long#1}}

```

```

81 </2ekernel | latexrelease>
82 <latexrelease>\EndIncludeInRelease
83 <latexrelease>\IncludeInRelease{0000/00/00}%
84 <latexrelease>    {\@star@or@long}{Macros without args are short}%
85 <latexrelease>
86 <latexrelease>\def\@star@or@long#1{%
87 <latexrelease>    \ifstar
88 <latexrelease>        {\let\l@ngrel@x\relax#1}%
89 <latexrelease>        {\let\l@ngrel@x\long#1}}
90 <latexrelease>
91 <latexrelease>\EndIncludeInRelease
92 <*2ekernel>

```

*(End of definition for \@star@or@long.)*

**\l@ngrel@x** This is either `\relax` or `\long` depending on whether the `*`-form of a definition command is being executed.

```
93 \let\l@ngrel@x\relax
```

*(End of definition for \l@ngrel@x.)*

**\pr@tectedrel@x** Same for the protection status.

```
94 \let\pr@tectedrel@x\relax
```

*(End of definition for \pr@tectedrel@x.)*

**\newcommand** User level `\newcommand`.

```
95 \def\newcommand{\@star@or@long\new@command}
```

**\new@command**

```
96 \def\new@command#1{%
97     \testopt{\@newcommand#1}0}
```

*(End of definition for \newcommand and \new@command.)*

**\@newcommand** Handling arguments for `\newcommand`.

```

\@argdef 98 \def\@newcommand#1[#2]{%
\@xargdef 99     \kernel@ifnextchar [{\@xargdef#1[#2]}%
100         {\@argdef#1[#2]}}

```

Define `#1` if it is definable.

Both here and in `\@xargdef` the replacement text is absorbed as an argument because if we are not allowed to make the definition we have to get rid of it completely.

```

101 \long\def\@argdef#1[#2]#3{%
102     \@ifdefinable #1{\@yargdef#1\@ne{#2}{#3}}

```

Handle the second optional argument.

```

103 \long\def\@xargdef#1[#2] [#3]#4{%
104     \@ifdefinable#1{%

```

Define the actual command to be:

```
\def\foo{\@protected@testopt\foo\\foo{default}}
```

where `\\foo` is a csname generated from applying `\csname` and `\string` to `\foo`, ie the actual name contains a backslash and therefore can't clash easily with existing command names. "Default" is the contents of the second optional argument of `(re)newcommand`.

```
105 \expandafter\def\expandafter#1\expandafter{%
106     \expandafter
107     \@protected@testopt
108     \expandafter
109     #1%
110     \csname\string#1\endcsname
111     {#3}}%
```

Now we define the internal macro ie `\\foo` which is supposed to pick up all arguments (optional and mandatory).

```
112 \expandafter\@yargdef
113 \csname\string#1\endcsname
114 \tw@
115 {#2}%
116 {#4}}}
```

(End of definition for `\@newcommand`, `\@argdef`, and `\@xargdef`.)

**`\@testopt`** This macro encapsulates the most common call to `\@ifnextchar`, saving several tokens each time it is used in the definition of a command with an optional argument. **#1** The code to execute in the case that there is a `[` need not be a single token but can be any sequence of commands that 'expects' to be followed by `[`. If this command were only used in `\newcommand` definitions then **#1** would be a single token and the braces could be omitted from `{#1}` in the definition below, saving a bit of memory.

```
117 \long\def\@testopt#1#2{%
118     \kernel@ifnextchar[#{1}{#1[{#2}]}}
```

(End of definition for `\@testopt`.)

**`\@protected@testopt`** Robust version of `\@testopt`. The extra argument (**#1**) must be a single token. If protection is needed the call expands to `\protect` applied to this token, and the 2nd and 3rd arguments are discarded (by `\@x@protect`). Otherwise `\@testopt` is called on the 2nd and 3rd arguments.

This method of making commands robust avoids the need for using up two csnames per command, the price is the extra expansion time for the `\ifx` test.

```
119 \def\@protected@testopt#1{%
120     \ifx\protect\@typeset@protect
121     \expandafter\@testopt
122     \else
123     \@x@protect#1%
124     \fi}
```

(End of definition for `\@protected@testopt`.)

**`\@yargdef`** These generate a primitive argument specification, from a L<sup>A</sup>T<sub>E</sub>X [*digit*] form; in fact *digit* can be anything such that `\number <digit>` is single digit.

**`\@yargdef`** Reorganised slightly so that `\renewcommand{\reserved@a}[1]{foo}` works. I am not sure this is worth it, as a following `\newcommand` would over-write the definition of `\reserved@a`.

Recall that L<sup>A</sup>T<sub>E</sub>X2.09 goes into an infinite loop with  
`\renewcommand[1]{\@tempa}{foo}`  
(DPC 6 October 93).

Reorganised again (DPC 1999). Rather than make a loop to construct the argument spec by counting, just extract the required argument spec by using a delimited argument (delimited by the digit). This is faster and uses less tokens. The coding is slightly odd to preserve the old interface (using `#2 = \tw@` as the flag to surround the first argument with `[]`). But the new method did not allow for the number of arguments `#3` not being given as an explicit digit; hence (further expansion of this argument and use of) `\number` was added later in 1999.

It is not clear why these are still `\long`.

```

125 \long \def \@yargdef #1#2#3{%
126   \ifx#2\tw@
127     \def\reserved@b##1{[####1]}%
128   \else

186   #2}
```

(End of definition for \@ifdefinable, \@@ifdefinable, and \@rc@ifdefinable.)

**\newenvironment**

Define a new user environment. #1 is the environment name. #2# Grabs all the tokens up to the first {. These will be any optional arguments. They are not parsed at this point, but are just passed to \@newenv which will eventually call \newcommand. Any optional arguments will then be parsed by \newcommand as it defines the command that executes the ‘begin code’ of the environment.

This #2# trick removed with version 1.2i as it fails if a { occurs in the optional argument. Now use \@ifnextchar directly.

```

187 \def\newenvironment{\@star@or@long\new@environment}

\new@environment 188 \def\new@environment#1{%
189   \@testopt{\@newenva#1}0}

```
209 \def\newif#1{%
210   \count@\escapechar \escapechar\m@ne
211   \let#1\iffalse
212   \@if#1\iftrue
213   \@if#1\iffalse
214   \escapechar\count@}
```

```
\@if 215 \def\@if#1#2{%
216   \expandafter\def\csname\expandafter\@gobbletwo\string#1%
217   \expandafter\@gobbletwo\string#2\endcsname
218   {\let#1#2}}
```

*(End of definition for \newif and \@if.)*

`\providecommand` `\providecommand` takes the same arguments as `\newcommand`, but discards them if #1 is already defined. Otherwise it just acts like `\newcommand`. This implementation currently leaves any discarded definition in `\reserved@a` (and possibly `\reserved@a`) this wastes a bit of space, but it will be reclaimed as soon as these scratch macros are redefined.

```
219 \def\providecommand{\@star@or@long\provide@command}
```

```
\provide@command 220 \def\provide@command#1{%
221   \begingroup
222   \escapechar\m@ne\xdef\@gtempa{\expandafter\string\@car#1?\@nil}}%
223   \endgroup
224   \expandafter\@ifundefined\@gtempa
225   {\def\reserved@a{\new@command#1}}%
226   {\def\reserved@a{\renew@command\reserved@a}}%
227   \reserved@a}%
```

*(End of definition for \providecommand and \provide@command.)*

`\CheckCommand` `\CheckCommand` takes the same arguments as `\newcommand`. If the command already exists, with the same definition, then nothing happens, otherwise a warning is issued. Useful for checking the current state before a macro package starts redefining things. Currently two macros are considered to have the same definition if they are the same except for different default arguments. That is, if the old definition was: `\newcommand\xxx[2][a]{(#1)(#2)}` then `\CheckCommand\xxx[2][b]{(#1)(#2)}` would *not* generate a warning, but, for instance `\CheckCommand\xxx[2]{(#1)(#2)}` would.

```
228 \def\CheckCommand{\@star@or@long\check@command}
```

`\CheckCommand` is only available in the preamble part of the document.

```
229 \@onlypreamble\CheckCommand
```

```
\check@command 230 \def\check@command#1#2#{\@check@c#1{#2}}
231 \@onlypreamble\check@command
```

*(End of definition for \CheckCommand and \check@command.)*

`\@check@c` `\CheckCommand` itself just grabs all the arguments we need, without actually looking for [ optional argument forms. Now define `\reserved@a`. If `\reserved@a` is then defined, compare it with the “`\#1`” otherwise compare `\reserved@a` with `\#1`.

```

232 \long\def\@check@c#1#2#3{%
233   \expandafter\let\csname\string\reserved@a\endcsname\relax
234   \renewcommand\reserved@a#2{#3}%
235   \@ifundefined{\string\reserved@a}%
236     {\@check@eq#1\reserved@a}%
237     {\expandafter\@check@eq
238       \csname\string#1\expandafter\endcsname
239       \csname\string\reserved@a\endcsname}}
240 \@onlypreamble\@check@c

```

*(End of definition for \@check@c.)*

`\@check@eq` Complain if `\#1` and `\#2` are not `\ifx` equal.

```

241 \def\@check@eq#1#2{%
242   \ifx#1#2\else
243     \@latex@warning@no@line
244       {Command \noexpand#1 has
245       changed.\MessageBreak
246       Check if current package is valid}%
247   \fi}
248 \@onlypreamble\@check@eq

```

*(End of definition for \@check@eq.)*

`\@gobble` The `\@gobble` macro is used to get rid of its argument.

```

\@gobbletwo 249 \long\def \@gobble #1{}
\@gobblethree 250 \long\def \@gobbletwo #1#2{}
\@gobblefour 251 \long\def \@gobblethree #1#2#3{}
252 \long\def \@gobblefour #1#2#3#4{}

```

*(End of definition for \@gobble and others.)*

There are also `\@gobble@om`, `\@gobble@som`, `\@gobble@with@sphack@om`, and `\@gobble@with@sphack@som`. They accept an optional and a mandatory argument, possibly preceeded by a star. In all cases the expansion is empty or just manipulates the spaces around the command. Used to disable commands such as `\index` or `\label` in certain situations. Since they are defined with `\DeclareDocumentCommand`, which is not yet available at this point, the actual definition happens in `ltsect.dtx`.

`\@firstofone` Some argument-grabbers.

```

\@firstoftwo 253 \long\def\@firstofone#1{#1}
\@secondoftwo 254 \long\def\@firstoftwo#1#2{#1}
255 \long\def\@secondoftwo#1#2{#2}

```

`\@iden` is another name for `\@firstofone` for compatibility reasons.

```

256 \let\@iden\@firstofone

```

*(End of definition for \@firstofone and others.)*

`\@iden`

`\@thirdofthree` Another grabber now used in the encoding specific section.

```

257 \long\def\@thirdofthree#1#2#3{#3}

```

(End of definition for \@thirdofthree.)

`\@expandtwoargs` A macro to totally expand two arguments to another macro

```
258 </2ekernel>
259 <latexrelease>\IncludeInRelease{2022/11/01}%
260 <latexrelease>      {\@expandtwoargs}{protected edef}%
261 <*2ekernel | latexrelease>
262 \def\@expandtwoargs#1#2#3{%

269 <latexrelease>\edef\reserved@a{\noexpand#1{#2}{#3}}\reserved@a}
270 <latexrelease>\EndIncludeInRelease
271 <*2ekernel>
```

(End of definition for \@expandtwoargs.)

`\@backslashchar` A category code 12 backslash.

```
272 \edef\@backslashchar{\expandafter\@gobble\string\\}
```

(End of definition for \@backslashchar.)

## 1.4 Robust commands and protect

Fragile and robust commands are one of the thornier issues in L<sup>A</sup>T<sub>E</sub>X's commands. Whilst typesetting documents, L<sup>A</sup>T<sub>E</sub>X makes use of many of T<sub>E</sub>X's features, such as arithmetic, defining macros, and setting variables. However, there are (at least) three different occasions when these commands are not safe. These are called 'moving arguments' by L<sup>A</sup>T<sub>E</sub>X, and consist of:

- writing information to a file, such as indexes or tables of contents.
- writing information to the screen.
- inside an `\edef`, `\message`, `\mark`, or other command which evaluates its argument fully.

The method L<sup>A</sup>T<sub>E</sub>X uses for making fragile commands robust is to precede them with `\protect`. This can have one of four possible values:

- `\relax`, for normal typesetting. So `\protect\foo` will execute `\foo`.
- `\string`, for writing to the screen. So `\protect\foo` will write `\foo`.
- `\noexpand`, for writing to a file. So `\protect\foo` will write `\foo` followed by a space.
- `\@unexpandable@protect`, for writing a moving argument to a file. So `\protect\foo` will write `\protect\foo` followed by a space. This value is also used inside `\edefs`, `\marks` and other commands which evaluate their arguments fully. More precisely, whenever the content of an `\edef` or `\xdef` etc. can contain arbitrary user input not under the direct control of the programmer, one should use `\protected@edef` instead of `\edef`, etc., so that `\protect` has a suitable definition and the user input will not break if it contains fragile commands.

`\@unexpandable@protect`

```
273 \def\@unexpandable@protect{\noexpand\protect\noexpand}
```

(End of definition for \@unexpandable@protect.)

```
\DeclareRobustCommand
\declare@robustcommand
\declare@robustcommand@auxi
\declare@robustcommand@auxii
\declare@robustcommand@auxiii
```

This is a package-writers command, which has the same syntax as `\newcommand`, but which declares a protected command. It does this by having

```
\DeclareRobustCommand\foo
define \foo to be \protect\foo<space>,
and then use \newcommand\foo<space>.
```

Since the internal command is `\foo<space>`, when it is written to an auxiliary file, it will appear as `\foo`.

We have to be a bit cleverer if we're defining a short command, such as `\_`, in order to make sure that the auxiliary file does not include a space after the command, since `\_ a` and `\_a` aren't the same. In this case we define `\_` to be:

```
\x@protect\_ \protect\_<space>
```

which expands to:

```
\ifx\protect\@typeset@protect\else
\x@protect@\_
\fi
\protect\_<space>
```

Then if `\protect` is `\@typeset@protect` (normally `\relax`) then we just perform `\_<space>`, and otherwise `\x@protect@` gobbles everything up and expands to `\protect\_`. None of that works with an active char (as we have only one character token to play with), so we resort to using the engine mechanism there. (The braces in passing #1 there are defensive in case someone has passed more than one token!)

*Note:* setting `\protect` to any value other than `\relax` whilst in 'typesetting' mode will cause commands to go into an infinite loop! In particular, setting `\protect` to `\@empty` will cause `\_` to loop forever. It will also break lots of other things, such as protected `\ifmmodes` inside `\haligns`. If you really have to do such a thing, then please set `\@typeset@protect` to be `\@empty` as well. (This is what the code for `\patterns` does, for example.)

More fun with `\expandafter` and `\csname`.

```
274 \def\DeclareRobustCommand{\@star@or@long\declare@robustcommand}
275 \def\declare@robustcommand#1{%
276   \ifx\@undefined#1\else\ifx\relax#1\else
277     \@latex@info{Redefining \string#1}%
278     \fi\fi
279   \ifcat\noexpand~\noexpand#1%
280     \expandafter\declare@robustcommand@auxi
281   \else
282     \expandafter\declare@robustcommand@auxiii
283   \fi
284   {#1}%
285 }
```

For active chars, we cannot use an auxiliary so have to ‘pack’ everything we need in one definition. To allow for use in file names, etc., we need `\ifincsname` in the definition, so we use two steps to grab that. We also take advantage of the need for an extra auxiliary to do some expansion to give us the string we will want.

```

286 \protected\long\def\declare@robustcommand@auxi#1#2#{%

352     \fi\protect#1%
353 }

```

(End of definition for `\DeclareRobustCommand` and others.)

`\@typeset@protect` We set `\@typeset@protect` to `\relax` rather than `\@empty` to make sure that the protection mechanism stops the look-ahead and expansion performed at the start of `\halign` cells.

```
354 \let\@typeset@protect\relax
```

(End of definition for `\@typeset@protect`.)

`\set@display@protect` These macros set `\protect` appropriately for typesetting or displaying.

```

\set@typeset@protect 355 \def\set@display@protect{\let\protect\string}
356 \def\set@typeset@protect{\let\protect\@typeset@protect}

```

(End of definition for `\set@display@protect` and `\set@typeset@protect`.)

`\protected@edef` The commands `\protected@edef` and `\protected@xdef` perform ‘safe’ `\edefs` and `\xdefs`, saving and restoring `\protect` appropriately. For cases where restoring `\protect` doesn’t matter, there’s an ‘unsafe’ `\unrestored@protected@xdef`, useful if you know what you’re doing!

`\protected@xdef`  
`\unrestored@protected@xdef`  
`\restore@protect`

```

357 \def\protected@edef{%
358     \let\@protect\protect
359     \let\protect\@unexpandable@protect
360     \afterassignment\restore@protect
361     \edef
362 }
363 \def\protected@xdef{%
364     \let\@protect\protect
365     \let\protect\@unexpandable@protect
366     \afterassignment\restore@protect
367     \xdef

```

```

368 }
369 \def\unrestored@protected@xdef{%
370   \let\protect\@unexpandable@protect
371   \xdef
372 }
373 \def\restore@protect{\let\protect\@protect}

```

*(End of definition for \protected@edef and others.)*

**\protect** The normal meaning of \protect

```

374 \set@typeset@protect

```

*(End of definition for \protect.)*

**\MakeRobust** This macro makes an existing fragile macro robust, but only if it hasn't been robust in the past, i.e., it checks for the existence of the macro `\<name>`<sub>␣</sub> and if that exists it assumes that `\<name>` is already robust. In that case either undefine the inner macro first or use `\DeclareRobustCommand` to define it in a robust way directly. We could probably test the top-level definition to have the right kind of structure, but this is somewhat problematical as we then have to distinguish between `\long` macros and others and also take into account that sometimes the top-level is deliberately done manually (like with `\begin`).

The macro firstly checks if the control sequence in question exists at all.

```

375 \</2ekernel>
376 \<latexrelease>\IncludeInRelease{2020/10/01}{\MakeRobust}{\MakeRobust}%
377 \<*2ekernel | latexrelease>
378 \def\MakeRobust#1{%
379   \count@=\escapechar
380   \escapechar='\\
381   \@ifundefined{\expandafter\@gobble\string#1}{%
382     \@latex@error{Command '\string#1' undefined.%
383     \MessageBreak There is nothing here to make robust}%
384     \@eha
385   }%

```

Then we check if the macro is already robust. We do this by testing if the internal name for a robust macro is defined, namely `\foo`<sub>␣</sub>. If it is already defined do nothing, otherwise set `\foo`<sub>␣</sub> equal to `\foo` and redefine `\foo` so that it acts like a macro defined with `\DeclareRobustCommand`. We use `\@kernel@rename@newcommand` to copy `\foo` over to `\foo`<sub>␣</sub>, including a possible default optional argument.

```

386   {%
387     \@ifundefined{\expandafter\@gobble\string#1\space}%
388     {%
389       \expandafter\@kernel@rename@newcommand
390       \csname\expandafter\@gobble\string#1\space\endcsname

```

This macro renames a command, possibly with an optional argument (defined with `\newcommand`) from #2 to #1, by renaming the internal macro `\\#2` to `\\#1` and defining `\\#1` appropriately, then undefining `\\#2` and `\\#2`. The `\afterassignment` trick is to make both definitions in `\@copy@newcommand` global (which are local by default).

In case the macro was defined with `\newcommand` and an optional argument, to replicate exactly the behaviour of `\DeclareRobustCommand` we have to move also the internal `\\foo` to `\\foo_`. In that case, #1 will be a parameterless macro (`\robust@command@chk@safe` checks that), and `\@if@newcommand` will return true (both defined below in this file). If so, we can use `\@copy@newcommand` rather than plain `\let` to copy the command over. `\@kernel@rename@newcommand` does this test and carries out the renaming.

```

**\kernel@make@fragile** The opposite of **\MakeRobust** except that it doesn't do many checks as it is internal to the kernel. Why does one want such a thing? Only for compatibility reasons if **latexrelease** requests a rollback of the kernel. For this reason we pretend that this command existed in all earlier versions of L<sup>A</sup>T<sub>E</sub>X i.e., we are not rolling it back since we need it precisely then. But we have to get it into the **latexrelease** file so that a roll forward is possible too.

```

## 1.5 Acting on robust commands

```

513 \</2ekernel>
514 \<latexrelease>\IncludeInRelease{2020-10-01}{\robust@command@act}
515 \<latexrelease>  {Add \robust@command@act}%
516 \<*2ekernel | latexrelease>

```

With most document level commands being robust now there is more of a requirement to have a standard way of aliasing (or copying) a command to a new name, for example to save an original definition before changing a command. `\DeclareCommandCopy` is analogous to  $\text{\TeX}$ ’s `\let`, except that it copes with the different types of robust commands defined by  $\text{\LaTeX}$ ’s mechanisms.

A couple of “types of robustness” are defined by the  $\text{\LaTeX} 2_{\epsilon}$  kernel, namely robust commands defined with `\DeclareRobustCommand` and commands with optional arguments defined with `\newcommand`. However there are other types of robust commands that are frequently used, which are not defined in the  $\text{\LaTeX} 2_{\epsilon}$  kernel, like commands defined with `xparse`’s `\NewDocumentCommand` and `etoolbox`’s `\newrobustcmd`.

In this section we will define a generic extensible machinery to act on robust commands. This code will then be used to test if a command is robust, considered the different types of robustness, and then either copy that definition, if `\DeclareCommandCopy` (or similar) is used, or show the definition of the command, if `\ShowCommand` is used.

`\robust@command@act` The looping machinery is generic and knows nothing about what is to be done for each case. The syntax of the main macro `\robust@command@act` is:

```
\robust@command@act⟨action-list⟩⟨robust-cmd⟩
⟨fallback-action⟩⟨act-arg⟩
```

`⟨action-list⟩` is a token list of the form:

```
{⟨if-type-1⟩ ⟨act-type-1⟩}
{⟨if-type-2⟩ ⟨act-type-2⟩}
...
```

`\robust@command@act` will iterate over the `⟨action-list⟩`, evaluating each `⟨if-type-n⟩` `⟨robust-cmd⟩` `{⟨true⟩}{⟨false⟩}`. If the `⟨if-type-n⟩` conditional returns `⟨true⟩`, then `⟨act-type-n⟩⟨act-arg⟩` is executed, and the loop ends. If the conditional returns `⟨false⟩`, then `⟨if-type-n + 1⟩` is executed in the same way, until either one of the conditionals return `⟨true⟩`, or the end of the `⟨action-list⟩` is reached. If the end is reached, then `⟨fallback-action⟩⟨act-arg⟩` is executed before `\robust@command@act` exits.

`\robust@command@act` will start by using `\robust@command@act@chk@args` to check if the `⟨robust-cmd⟩` (#2) is a parameterless (possibly `\protected`) macro. If it is not, the command is not a robust command: these always start with a parameterless user-level macro; in that case, `\robust@command@act@end` is used to short-circuit the process and do the `⟨fallback-action⟩` (#3). This first test is necessary because later on we need to be able to expand the `⟨robust-cmd⟩` without the risk of it Breaking Badly, and as a bonus, this speeds up the process in case we used `\NewCommandCopy` in a “normal” macro.

```
517 \long\def\robust@command@act#1#2#3#4{%
518   \robust@command@chk@safe#2%
519   {\expandafter\robust@command@act@loop
520    \expandafter#2%
521    #1{\@nnil\@nnil}%
522    \robust@command@act@end}%
523   {\robust@command@act@end}%
524   {#3}{#4}}%
```

If `\robust@command@act@chk@args` branched to false, then `\robust@command@act@loop` will loop over the list of items in the `⟨action-list⟩` (#1), and process each item as described earlier. If the `⟨if-type-n⟩` command expands to `⟨true⟩` then `\robust@command@act@do` is used to execute `⟨act-type-n⟩` on the `⟨act-arg⟩`, otherwise the loop resumes with the next item.

```
525 \long\def\robust@command@act@loop#1#2{\robust@command@act@loop@aux#1#2}
526 \long\def\robust@command@act@loop@aux#1#2#3{%

### 1.5.1 Copying robust commands

```

563 </2ekernel>
564 <latexrelease>\IncludeInRelease{2020-10-01}{\DeclareCommandCopy}
565 <latexrelease> {Add \NewCommandCopy, \RenewCommandCopy, and \DeclareCommandCopy}%
566 <*2ekernel | latexrelease>

```

`\NewCommandCopy` `\NewCommandCopy` starts by checking if `#1` is already defined, and raises an error if so, otherwise the definition is carried out. `\RenewCommandCopy` does (almost) the opposite. `\DeclareCommandCopy` If the command is *not* defined, then an error is raised. But the definition is carried out anyhow, so the behaviour is consistent with `\renewcommand`.

A `\ProvideCommandCopy` isn't defined because it's not reasonably useful. `\provide...` commands mean “define this if there's no other definition”, but copying a command (usually) implies that the command being copied is defined, so `\ProvideCommandCopy` doesn't make a lot of sense. But more importantly, the most common use case of copying a command is to redefine it later, while preserving the old definition, as in:

```

\ProvideCommandCopy \A \B
\renewcommand \B { ... \A ... }

```

then, if \A is already defined the first line is skipped, and in this case \B won't work as expected.

The three versions call the internal `\declare@commandcopy` with the proper action. `\@firstofone` will carry out the copy. The only case when the copy is not made is the `<false>` case for `\NewCommandCopy`, in which the command already exists and the definition is aborted.

```

567 \def\NewCommandCopy{%
568   \declare@commandcopy
569     {\@firstofone}%
570     {\@firstoftwo\@notdefinable}}
571 \def\RenewCommandCopy{%
572   \declare@commandcopy
573     {\@latexerror{Command \backslashchar\reserved@a\space undefined}\@ehc
574     \@firstofone}%
575     {\@firstofone}}
576 \def\DeclareCommandCopy{%
577   \declare@commandcopy
578     {\@firstofone}%
579     {\@firstofone}}

```

Start by checking if the command is already defined. The proper action is taken by each specific command above. If all's good, then `\robust@command@act` is called with the proper arguments as described earlier, with `\@declarecommandcopylisthook` as the `<action-list>` and `\declare@commandcopy@let` as the `<fallback-action>`.

```

\declare@commandcopy
\declare@commandcopy@do
580 \long\def\declare@commandcopy#1#2#3#4{%
581   \edef\reserved@a{\expl@cs@to@str@N#3}%
582   \@ifundefined\reserved@a{#1}{#2}%
583     {\declare@commandcopy@do{#3}{#4}}
584 \long\def\declare@commandcopy@do#1#2{%
585   \robust@command@act
586     \@declarecommandcopylisthook#2%

636 <*2ekernel>

```

(End of definition for \NewEnvironmentCopy, \RenewEnvironmentCopy, and \DeclareEnvironmentCopy.)

## 1.5.2 Showing robust commands

`\ShowCommand` Most of the machinery defined for `\NewCommandCopy` can be used to show the definition of a robust command, in a similar fashion to `\texdef`. The difference is that after the command is detected to have a given type of robustness, rather than making a copy, we use a separate routine to show its definition.

With all the machinery in place, `\ShowCommand` itself is quite simple: we use `\robust@command@act` to iterate through the `\@showcommandlisthook` list, and if nothing is found, fallback to `\show`.

```

637 </2ekernel>
638 <latexrelease>\IncludeInRelease{2020-10-01}{\ShowCommand}%
639 <latexrelease> {Add \ShowCommand}%
640 <*2ekernel | latexrelease>

641 \long\def\ShowCommand#1{%
642   \robust@command@act
643   \@showcommandlisthook#1%
644   \show#1}

```

`\@showcommandlisthook` The initial definition of `\@showcommandlisthook` contains the same tests as used for copying, but `\@show@...` commands instead of `\@copy@...`. Same as before, it is initialized to cope with `\DeclareRobustCommand` and `\newcommand` with optional arguments.

```

645 \def\@showcommandlisthook{%
646   {\@if@DeclareRobustCommand \@show@DeclareRobustCommand}%
647   {\@if@newcommand \@show@newcommand}}

```

Now the rollback code.

660 <latexrelease>       \@show@DeclareRobustCommand, \@show@newcommand}%
661 <*2ekernel | latexrelease>

```

## 1.5.3 Commands defined with \DeclareRobustCommand

`\@if@DeclareRobustCommand` Now that we provided a generic way to copy one macro to another, we need to define a way to check if a command is one of L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub>'s robust types. These tests are heavily based on Heiko's `\LetLtxMacro`, but chopped into separate macros.

The command `\@if@DeclareRobustCommand` checks if a command `\cmd` was defined by `\DeclareRobustCommand`. The test returns true if the expansion of `\cmd` is exactly `\protect\cmd_`.

```

662 \long\def\@if@DeclareRobustCommand#1{%

```

```

663 \begingroup
664 \escapechar='\\
665 \edef\reserved@a{\string#1}%
666 \edef\reserved@b{\detokenize{#1}}%
667 \xdef\@gtempa{%
668     \ifx\reserved@a\reserved@b
669         \noexpand\x@protect
670         \noexpand#1%
671     \fi
672     \noexpand\protect
673     \expandafter\noexpand\csname\@expl@cs@to@str@@N#1 \endcsname}%
674 \endgroup
675 \ifx\@gtempa#1\relax
676     \expandafter\@firstoftwo
677 \else
678     \expandafter\@secondoftwo
679 \fi}

```

If a command was defined by `\DeclareRobustCommand` (that is, `\@if@DeclareRobustCommand` returns true), then to make a copy of `\cmd` into `\foo` we define the latter such that it expands to `\protect\foo`, then make `\foo` equal to `\cmd`.

There is one detail we need to take care of: if a command was defined with `\DeclareRobustCommand` it may still have an optional argument, in which case there is one more macro layer before the actual definition of the command. We use `\@if@newcommand` to check that and `\@copy@newcommand` to do the copying.

```

680 \long\def\@copy@DeclareRobustCommand#1#2{%
681     \begingroup
682     \escapechar='\\
683     \edef\reserved@a{\string#1}%
684     \edef\reserved@b{\detokenize{#1}}%
685     \edef\reserved@a{%
686     \endgroup
687     \def\noexpand#1{%
688         \ifx\reserved@a\reserved@b
689             \noexpand\x@protect
690             \noexpand#1%
691         \fi
692         \noexpand\protect
693         \expandafter\noexpand\csname\@expl@cs@to@str@@N#1 \endcsname}%
694     \noexpand\copy@kernel@robust@command
695     \expandafter\noexpand\csname\@expl@cs@to@str@@N#1 \endcsname
696     \expandafter\noexpand\csname\@expl@cs@to@str@@N#2 \endcsname}%
697     \reserved@a}
698 \long\def\copy@kernel@robust@command#1#2{%
699     \robust@command@chk@safe#2%
700     {\@if@newcommand#2%
701     {\@copy@newcommand}%
702     {\declare@commandcopy@let}}
703     {\declare@commandcopy@let}%
704     #1#2}

```

Showing the command is pretty simple. This command prints the top-level expansion as  $\TeX$ 's `\show` would, but with robust macro: rather than just `macro:`, then

```

\@show@DeclareRobustCommand
\show@kernel@robust@command
\@show@macro

```

a blank line and then `\show` the inner command. For a macro defined with, say, `\DeclareRobustCommand\foo[1]{bar}`, it will print:

```
> \foo=robust macro:
->\protect \foo .

> \foo =\long macro:
#1->bar.
```

If the inner command is defined with an optional argument, then `\@show@newcommand` is also used.

The value of `\escapechar` is deliberately not enforced, so `\ShowCommand` behaves more like `\show`.

```
705 \long\def\@show@DeclareRobustCommand#1{%
706   \typeout{> \string#1=robust macro:}%
707   \typeout{->\@expl@cs@replacement@spec@@N#1.^~J}%
708   \expandafter\show@kernel@robust@command
709     \csname\@expl@cs@to@str@@N#1 \endcsname}
710 \long\def\show@kernel@robust@command#1{%
711   \robust@command@chk@safe#1%
712     {\@if@newcommand#1%
713       {\@show@newcommand}%
714       {\@show@macro}}%
715     {\@show@macro}%
716   #1}
717 \let\@show@macro\show
```

(End of definition for `\@if@DeclareRobustCommand` and others.)

#### 1.5.4 Commands defined with `\newcommand` (with optional argument)

`\@if@newcommand` A command `\cmd` (or `\cmdL`, if it was defined with `\DeclareRobustCommand`) with an optional argument will expand to `\@protected@testopt\cmd\cmd{<opt>}`. To check that we look at the first three tokens in the expansion of `\cmd`, and return true or false accordingly.

This test *requires* that the command be a parameterless macro, otherwise it will not work (and probably break). This is ensured with `\robust@command@chk@safe` before calling `\@if@newcommand`.

```
718 \long\def\@if@newcommand#1{%
719   \edef\reserved@a{%
720     \noexpand\@protected@testopt
721     \noexpand#1%
722     \expandafter\noexpand\csname\@backslashchar\@expl@cs@to@str@@N#1\endcsname}%
723   \edef\reserved@b{%
724     \unexpanded\expandafter\expandafter\expandafter
725       {\expandafter\@carcube#1{-}{-}{-}\@nil}}%
726   \ifx\reserved@a\reserved@b
727     \expandafter\@firstoftwo
728   \else
729     \expandafter\@secondoftwo
730   \fi}
```

Then, if a command `\cmd` takes an optional argument, we copy it to `\foo` by defining the latter to expand to `\@protected@testopt\foo\foo{<opt>}`.

```
\@copy@newcommand
731 \long\def\@copy@newcommand#1#2{%
732   \edef#1{\noexpand\@protected@testopt
733     \noexpand#1%
734     \expandafter\noexpand\csname\@backslashchar\@expl@cs@to@str@@N#1\endcsname
735     \unexpanded\expandafter\expandafter\expandafter
736       {\expandafter\@gobblethree#2}}%
737   \expandafter
738   \let\csname\@backslashchar\@expl@cs@to@str@@N#1\expandafter\endcsname
739     \csname\@backslashchar\@expl@cs@to@str@@N#2\endcsname}
```

`\@show@newcommand`  
`\@show@newcommand@aux`

A command being `\shown` here is guaranteed to have an optional argument. Start by showing the top-level expansion of the command (using `\typeout` to avoid TeX asking for interaction and extra context lines), then call `\@show@newcommand@aux` with the internal command, which contains the actual definition, and with the expansion of the command to extract the default value of the optional argument.

```
740 \long\def\@show@newcommand#1{%
741   \typeout{> \string#1=robust macro:}%
742   \typeout{->\@expl@cs@replacement@spec@@N#1.^^J}%
743   \expandafter\@show@newcommand@aux
744     \csname\@backslashchar\@expl@cs@to@str@@N#1\expandafter\endcsname
745     \expandafter{#1}\@show@tokens}
```

For a macro defined with, say, `\newcommand\foo[1][opt]{bar}`, it will print:

```
> \foo=robust macro:
->\@protected@testopt \foo \foo {opt}.

> \foo=\long macro:
> default #1=opt.
[#1]->bar.
```

If the command was defined with `\DeclareRobustCommand`, then another pair of lines show the top-level expansion `\protect_\foo_\_`.

```
746 \long\def\@show@newcommand@aux#1#2#3{%
747   \typeout{> \string#1=\@expl@cs@prefix@spec@@N#1macro:}%
748   #3{default \string##1=\expandafter\detokenize\@gobblethree#2.^^J%
749     \@expl@cs@parameter@spec@@N#1->\@expl@cs@replacement@spec@@N#1}}
```

This macro prints the contents of the token list (macro) `#1` using `\showtokens`. The `\expandafter` gymnastics ensures that `\showtokens` itself, and the internals of this macro aren't showed in the context lines.

```
\@show@tokens
750 \long\def\@show@tokens#1{%
751   \edef\reserved@a{#1}%
752   \showtokens\expandafter
753     \expandafter\expandafter{\expandafter\reserved@a}}
```

Now the rollback code.

```
754 </2ekernel | latexrelease>
755 <latexrelease>\EndIncludeInRelease
756 <latexrelease>\IncludeInRelease{0000-00-00}{\@if@DeclareRobustCommand}
757 <latexrelease> {Undefine \@if@DeclareRobustCommand, \@if@newcommand,
```

```

758 <latexrelease> \copy@DeclareRobustCommand, \copy@newcommand,
759 <latexrelease> \show@DeclareRobustCommand, \show@newcommand}%
760 <latexrelease>\let\@if@DeclareRobustCommand\@undefined

771 <*2ekernel>

```

(End of definition for \@if@newcommand and others.)

### 1.5.5 Showing environments

\ShowEnvironment

```

772 </2ekernel>
773 <latexrelease>\IncludeInRelease{2023-06-01}{\ShowEnvironment}
774 <latexrelease> {Add \ShowEnvironment}%
775 <*2ekernel | latexrelease>

```

\ShowEnvironment is quite similar to \ShowCommand. We will pass the environment `<env>` around as the macro `\env`, because `\robust@command@act` expects a single token.

```

776 \def\ShowEnvironment#1{%
777   \expandafter\@show@environment\csname #1\endcsname}
778 \long\def\@show@environment#1{%
779   \robust@command@act
780   \@showenvironmentlisthook#1%
781   \@show@normalenv#1}

```

This is similar to `\@showcommandlisthook`, but uses the dedicated versions for environments.

```

782 \def\@showenvironmentlisthook{%
783   {\@if@DeclareRobustCommand \show@DeclareRobustCommand@env}%
784   {\@if@newcommand \show@newcommand@env}}

```

These are similar to the command versions below, except they say “environment” and call `\@show@environment@end` to print the `\end` part.

\show@newcommand@env  
\show@DeclareRobustCommand@env

```

785 \long\def\@show@newcommand@env#1{%
786   \@show@environment@begin#1%
787   \expandafter\@show@newcommand@aux
788   \csname\@backslashchar\@expl@cs@to@str@@N#1\expandafter\endcsname
789   \expandafter{#1}\@show@typeout
790   \@show@environment@end#1}
791 \long\def\@show@DeclareRobustCommand@env#1{%
792   \@show@environment@begin#1%
793   \begingroup
794   \let\@show@tokens\@show@typeout
795   \let\@show@macro\@show@nonstop
796   \expandafter\show@kernel@robust@command

```

```

797 \csname\@expl@cs@to@str@N#1 \endcsname
798 \endgroup
799 \@show@environment@end#1}
800 \long\def\@show@environment@begin#1{%
801 \typeout{> \string\begin{\@expl@cs@to@str@N#1}=environment:}%
802 \typeout{\@expl@cs@parameter@spec@N#1->%
803 \@expl@cs@replacement@spec@N#1.^^J}}

```

A “normal” environment is straightforward. `\@show@environment@end` needs to check if the `\end` part is defined and show it accordingly, otherwise the output would show gibberish.

`\@show@normalenv`  
`\@show@environment@end`

```

804 \long\def\@show@normalenv#1{%
805 \show@environment@begin#1%
806 \show@environment@end#1}
807 \long\def\@show@environment@end#1{%
808 \expandafter\@show@environment@end@aux
809 \csname end\@expl@cs@to@str@N#1\endcsname#1}
810 \long\def\@show@environment@end@aux#1#2{%
811 \show@tokens{\string\end{\@expl@cs@to@str@N#2}%
812 \ifx\relax#1=undefined%
813 \else:^^J\@expl@cs@parameter@spec@N#1->%
814 \@expl@cs@replacement@spec@N#1%
815 \fi}}

```

And here some auxiliaries:

`\@show@nonstop`  
`\@show@typeout`

`\@show@nonstop` same output as `\show`, but doesn’t stop for interaction;  
`\@show@typeout` same output as `\showtokens`, but doesn’t stop for interaction.

```

816 \def\@show@nonstop#1{%
817 \typeout{> \string#1=\@expl@cs@prefix@spec@N#1macro:^^J%
818 \@expl@cs@parameter@spec@N#1->\@expl@cs@replacement@spec@N#1.}}
819 \def\@show@typeout#1{\typeout{> #1.^^J}}

```

Now the rollback code.

```

820 </2ekernel | latexrelease>
821 <latexrelease>\EndIncludeInRelease
822 <latexrelease>\IncludeInRelease{0000-00-00}{\ShowEnvironment}
823 <latexrelease> {Undefine \ShowEnvironment}%
824 <latexrelease>\let\ShowEnvironment\@undefined
825 <latexrelease>\EndIncludeInRelease
826 <*2ekernel>

```

*(End of definition for \ShowEnvironment and others.)*

## 1.6 Internal defining commands

These commands are used internally to define other L<sup>A</sup>T<sub>E</sub>X commands.

`\@ifundefined` Check if first arg is undefined or `\relax` and execute second or third arg depending,

```

827 </2ekernel>
828 <latexrelease>\IncludeInRelease{2018-04-01}{\@ifundefined}
829 <latexrelease>\Leave commands undefined in \@ifundefined}%
830 <*2ekernel | latexrelease>

```

Version using `\ifcsname` to avoid defining undefined tokens to `\relax`. Defined here to simplify using unmatched `\fi`.

```

831 \def\@ifundefined#1{%
832   \ifcsname#1\endcsname\@ifundefined@i\else\@ifundefined@ii\fi{#1}}
833 \long\def\@ifundefined@i#1\fi#2{\fi
834   \expandafter\ifx\csname #2\endcsname\relax
835     \@ifundefined@ii
836   \fi
837   \@secondoftwo}
838 \long\def\@ifundefined@ii\fi#1#2#3{\fi #2}

```

Now test of engine.

```
839 \ifx\numexpr\@undefined
```

Classic version (should not be needed as etex is assumed).

```

840 \def\@ifundefined#1{%
841   \expandafter\ifx\csname#1\endcsname\relax
842     \expandafter\@firstoftwo
843   \else
844     \expandafter\@secondoftwo
845   \fi}
846 \else\ifx\directlua\@undefined

```

Use the `\ifcsname` defined above.

```
847 \else
```

Optimised version for LuaTeX, using `\lastnamedcs`

```

848 \def\@ifundefined#1{%
849   \ifcsname#1\endcsname
850     \expandafter\ifx\lastnamedcs\relax\else\@ifundefined@i\fi
851   \fi
852   \@firstoftwo}
853 \long\def\@ifundefined@i#1#2#3#4#5{#1#2#5}
854 \fi
855 \fi
856 </2ekernel | latexrelease>
857 <latexrelease>\EndIncludeInRelease
858 <latexrelease>\IncludeInRelease{0000-00-00}{\@ifundefined}
859 <latexrelease>\Leave commands undefined in \@ifundefined}%
860 <latexrelease>\def\@ifundefined#1{%
861 <latexrelease>   \expandafter\ifx\csname#1\endcsname\relax
862 <latexrelease>     \expandafter\@firstoftwo
863 <latexrelease>   \else
864 <latexrelease>     \expandafter\@secondoftwo
865 <latexrelease>   \fi}
866 <latexrelease>\EndIncludeInRelease
867 <*2ekernel>

```

*(End of definition for \@ifundefined.)*

`\@qend` The following define `\@qend` and `\@qrelax` to be the strings ‘end’ and ‘relax’ with the characters `\catcoded 12`.

```

868 \edef\@qend{\expandafter\@cdr\string\end\@nil}
869 \edef\@qrelax{\expandafter\@cdr\string\relax\@nil}

```

(End of definition for \@qend and \@qrelax.)

**\@ifnextchar** \@ifnextchar peeks at the following character and compares it with its first argument. If both are the same it executes its second argument, otherwise its third.

```
870 \long\def\@ifnextchar#1#2#3{%  
871   \let\reserved@d=#1%  
872   \def\reserved@a{#2}%  
873   \def\reserved@b{#3}%  
874   \futurelet\@let@token\@ifnch}
```

(End of definition for \@ifnextchar.)

**\kernel@ifnextchar** This macro is the kernel version of \@ifnextchar which is used in a couple of places to prevent the AMS variant from being used since in some places this produced chaos. For example, if an fd file is loaded in a random place then the optional argument to \ProvidesFile could get printed there instead of being written only in the log file. This happened when there was a space or a newline between the mandatory and optional arguments! It should really be fixed in the amsmath package one day, but...

Note that there may be other places in the kernel where this version should be used rather than the original, but variable, version.

```
875 \let\kernel@ifnextchar\@ifnextchar
```

(End of definition for \kernel@ifnextchar.)

**\@ifnch** \@ifnch is a tricky macro to skip any space tokens that may appear before the character in question. If it encounters a space token, it calls xifnch.

```
876 \def\@ifnch{%  
877   \ifx\@let@token\@sptoken  
878     \let\reserved@c\@xifnch  
879   \else  
880     \ifx\@let@token\reserved@d  
881       \let\reserved@c\reserved@a  
882     \else  
883       \let\reserved@c\reserved@b  
884     \fi  
885   \fi  
886   \reserved@c}
```

(End of definition for \@ifnch.)

**\@sptoken** The following code makes \@sptoken a space token. It is important here that the control sequence \: consists of a non-letter only, so that the following whitespace is significant. Together with the fact that the equal sign in a \let may be followed by only one optional space the desired effect is achieved. NOTE: the following hacking must precede the definition of \: as math medium space.

```
887 \def\:{\let\@sptoken= } \: % this makes \@sptoken a space token
```

(End of definition for \@sptoken.)

**\@xifnch** In the following definition of \@xifnch, \: is again used to get a space token as delimiter into the definition.

```
888 \def\:{\@xifnch} \expandafter\def\: {\futurelet\@let@token\@ifnch}
```

(End of definition for \@xifnch.)

`\@ifstar` The new implementation below avoids passing the `<true code>` Through one more `\def` than the `<false code>`, which previously meant that `#` had to be written as `####` in one argument, but `##` in the other. The `*` is gobbled by `\@firstoftwo`.

```
889 \def\@ifstar#1{\@ifnextchar *{\@firstoftwo{#1}}}
```

(End of definition for `\@ifstar`.)

`\@dblarg`

```
\@xdblarg 890 \long\def\@dblarg#1{\kernel@ifnextchar[{\#1}{\@xdblarg{#1}}}
```

```
891 \long\def\@xdblarg#1#2{\#1[\#2]{\#2}}
```

(End of definition for `\@dblarg` and `\@xdblarg`.)

`\@sanitize` The command `\@sanitize` changes the catcode of all special characters except for braces to ‘other’. It can be used for commands like `\index` that want to write their arguments verbatim. Needless to say, this command should only be executed within a group, or chaos will ensue.

```
892 \def\@sanitize{\@makeother\ \@makeother\\\@makeother$\@makeother\&%
```

```
893 \@makeother\#\@makeother\^\@makeother\_ \@makeother%\@makeother\~}
```

(End of definition for `\@sanitize`.)

`\@onelevel@sanitize` This makes the whole “meaning” of `#1` (its one-level expansion) into catcode 12 tokens: it could be used in `\DeclareRobustCommand`.

If it is to be used on default float specifiers, this should be done when they are defined.

```
894 \def \@onelevel@sanitize #1{%
895   \edef #1{\expandafter\strip@prefix
896             \meaning #1}%
897 }
```

(End of definition for `\@onelevel@sanitize`.)

`\string@makeletter` Iterates through a string, turning each alphabetic character into a catcode-11 token (partly undoes a `\detokenize`). Useful for `\ifx`-based string comparisons where `\detokenize`-ing the other string would break too much code.

The macro uses `expl3`’s `\@expl@str@map@function@NN` to iterate on the string (without losing spaces) and applies `\string@makeletter` on each character. The latter checks if character is between `a–z` or `A–Z`, and uses `\@alph` or `\@Alph` to get the corresponding catcode-11 token. Other tokens are passed through unchanged.

```
898 </2ekernel>
899 <latexrelease>\IncludeInRelease{2020/10/01}{\string@makeletter}
900 <latexrelease> {Add \string@makeletter}%
901 <*2ekernel|latexrelease>
902 \def\string@makeletter#1{%
903   \@expl@str@map@function@NN#1\string@makeletter}
904 \def\@string@makeletter#1{%
905   \@char@if@alph{#1}%
906   {\@expl@char@generate@nn{‘#1’}{11}}%
907   {#1}}
908 \def\@char@if@alph#1{%
909   \ifnum0\ifnum‘#1<‘A 1\fi\ifnum‘#1>‘z 1\fi
910   \if\ifnum‘#1>‘Z \@fi\ifnum‘#1<‘a \@fi01\fi>0
```

```

911     \expandafter\@secondoftwo
912     \else
913     \expandafter\@firstoftwo
914     \fi}
915 </2ekernel | latexrelease>
916 <latexrelease>\EndIncludeInRelease
917 %
918 <latexrelease>\IncludeInRelease{0000/00/00}{\string@makeletter}
919 <latexrelease> {Undefine \string@makeletter}%
920 <latexrelease>\let\string@makeletter\@undefined
921 <latexrelease>\let\@string@makeletter\@undefined
922 <latexrelease>\let\char@if@alph\@undefined
923 <latexrelease>\EndIncludeInRelease
924 <*2ekernel>

(End of definition for \string@makeletter, \@string@makeletter, and \char@if@alph.)

```

`\makeatletter` Make internal control sequences accessible or inaccessible.

```

\makeatother 925 \DeclareRobustCommand\makeatletter{\catcode'\@11\relax}
926 \DeclareRobustCommand\makeatother{\catcode'\@12\relax}

```

(End of definition for `\makeatletter` and `\makeatother`.)

## 2 Discretionary Hyphenation

`\-`  
`\@dischph`

Moved here to be after the definition of `\DeclareRobustCommand`.

The primitive `\-` command adds a discretionary hyphen using the current font's `\hyphenchar`. Monospace fonts are usually declared with `\hyphenchar` set to `-1` to suppress hyphenation.

L<sup>A</sup>T<sub>E</sub>X, from L<sup>A</sup>T<sub>E</sub>X 2.09 in 1986 defined `\-` by

```
\def\-\{\discretionary{-}{-}{-}}
```

The following comment was added when these commands were first set up, 19 April 1986:

the `\-` command is redefined to allow it to work in the `\ttfamily` type style, where automatic hyphenation is suppressed by setting `\hyphenchar` to `-1`. The original primitive T<sub>E</sub>X definition is saved as `\@@hyph` just in case anyone needs it.

L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub>, between 1993 and 2017, had a comment at this point saying that the definition “would probably change” because the definition always uses `-`. The definition used below was given in comments at this point during time.

In 2017 we finally enabled this definition by default, with the older L<sup>A</sup>T<sub>E</sub>X definition accessible via `latexrelease` as usual.

In LuaL<sup>A</sup>T<sub>E</sub>X the primitive definition of `\-` is used directly because it's use of extended hyphenation parameters means that `\-` works correctly even with `\hyphenchar` set to `-1`. This change makes `\-` under LuaL<sup>A</sup>T<sub>E</sub>X compatible with language specific hyphenation characters.

Temporary definition of `\@latex@info`, final definition is later.

```
927 \def\@latex@info#1{}
```

```

928 </2ekernel>
929 <latexrelease>\IncludeInRelease{2020/10/01}{\-\-}{Use primitive \- in Lua\LaTeX}%
930 <*2ekernel | latexrelease>
931 \ifx\directlua\undefined
932   \DeclareRobustCommand{\-\-}{%
933     \discretionary{%
934       \char \ifnum\hyphenchar\font<\z@
935         \defaultthyphenchar
936       \else
937         \hyphenchar\font
938       \fi
939     }{}{}%

## File 07

# ltxcmd.dtx

## 1 Creating document commands

Document commands should be created using the tools provided by this module: `\NewDocumentCommand`, etc., in almost all cases. This allows clean separation of document-level syntax from code-level interfaces. Users have a need to create new document commands, and as such a significant amount of documentation for `ltxcmd` is provided as part of `usrguide3`. Here, additional material aimed at programmers is provided

```
1 <@@=cmd>
2 <*2ekernel>
3 \message{document commands,}
4 </2ekernel>
```

`ltxcmd` code contains an `^^@` character, which usually has catcode 15, so `\IncludeInRelease` will break when this code is being skipped, so we'll save the catcode of `^^@` to restore later:

```
5 <*2ekernel | latexrelease>
6 <latexrelease>\edef\@latexrelease@catcode@null{\the\catcode'\^^@ }
7 <latexrelease>\catcode'\^^@=12
8 \ExplSyntaxOn
9 <latexrelease>\NewModuleRelease{2020/10/01}{ltxcmd}
10 <latexrelease>{Document~command~parser}%
11 \cs_generate_variant:Nn \tl_head:n { e }
```

### 1.1 Variables and constants

---

<code>\l__cmd_arg_spec_tl</code>	Holds the argument specification after normalization of shorthands.
----------------------------------	---

---

```
12 \tl_new:N \l__cmd_arg_spec_tl
```

---

<code>\l__cmd_args_tl</code>	Token list variable for grabbed arguments.
------------------------------	--

---

```
13 \tl_new:N \l__cmd_args_tl
```

---

<code>\l__cmd_args_i_tl</code> <code>\l__cmd_args_ii_tl</code>	Hold the modified arguments when dealing with default values or processors.
---	---

---

```
14 \tl_new:N \l__cmd_args_i_tl
15 \tl_new:N \l__cmd_args_ii_tl
```

---

<code>\l__cmd_current_arg_int</code>	The number of the current argument being set up: this is used to make sure there are at most 9 arguments, then for creating the expandable auxiliary functions and knowing how many arguments the code function should take.
--------------------------------------	--

---

```
16 \int_new:N \l__cmd_current_arg_int
```

<u>\l__cmd_total_args_int</u>	<p>The total number of arguments found during normalization: this is required where special action is needed for the penultimate argument.</p> <pre>17 \int_new:N \l__cmd_total_args_int</pre>
<u>\l__cmd_last_mandatory_arg_int</u>	<p>Needed to allow handling of verbatim catcodes at the end of the setup.</p> <pre>18 \int_new:N \l__cmd_last_mandatory_arg_int</pre>
<u>\l__cmd_defaults_bool</u> <u>\l__cmd_defaults_tl</u>	<p>The boolean indicates whether there are any argument with default value other than -NoValue-; the token list holds the code to determine these default values in terms of other arguments.</p> <pre>19 \bool_new:N \l__cmd_defaults_bool 20 \tl_new:N \l__cmd_defaults_tl</pre>
<u>\l__cmd_environment_bool</u>	<p>Generating environments uses the same mechanism as generating functions. However, full processing of arguments is always needed for environments, and so the function-generating code needs to know this. This variable is also used at run time to give correct error messages.</p> <pre>21 \bool_new:N \l__cmd_environment_bool</pre>
<u>\l__cmd_environment_str</u>	<p>Name of the environment, used at definition time and at run time.</p> <pre>22 \str_new:N \l__cmd_environment_str</pre>
<u>\l__cmd_expandable_bool</u>	<p>Used to indicate if an expandable command is begin generated, as this affects both the acceptable argument types and how they are implemented.</p> <pre>23 \bool_new:N \l__cmd_expandable_bool</pre>
<u>\l__cmd_expandable_aux_name_tl</u>	<p>Used to create pretty-printing names for the auxiliaries: although the immediate definition does not vary, the full expansion does and so it does not count as a constant.</p> <pre>24 \tl_new:N \l__cmd_expandable_aux_name_tl 25 \tl_set:Nn \l__cmd_expandable_aux_name_tl 26   { 27     \l__cmd_function_tl \c_space_tl 28     ( arg~ \int_use:N \l__cmd_current_arg_int ) 29   }</pre>
<u>\g__cmd_grabber_int</u>	<p>Used (in exceptional cases) to get unique names for grabbers used by expandable commands.</p> <pre>30 \int_new:N \g__cmd_grabber_int</pre>

---

\l\_\_cmd\_fn\_tl For passing the pre-formed name of the auxiliary to be used as the parsing function.

31 \tl\_new:N \l\_\_cmd\_fn\_tl

---

\l\_\_cmd\_fn\_code\_tl For passing the pre-formed name of the auxiliary that contains the actual code.

32 \tl\_new:N \l\_\_cmd\_fn\_code\_tl

---

\l\_\_cmd\_function\_tl Holds the control sequence name of the function currently being defined: used to avoid passing this as an argument and to avoid repeated use of \cs\_to\_str:N.

33 \tl\_new:N \l\_\_cmd\_function\_tl

---

\l\_\_cmd\_grab\_expandably\_bool

When defining a non-expandable command, indicates whether the arguments can all safely be grabbed by expandable grabbers. This is to support abuses of `xparse` that use protected functions inside `csname` constructions.

34 \bool\_new:N \l\_\_cmd\_grab\_expandably\_bool

---

\l\_\_cmd\_obey\_spaces\_bool For trailing optionals.

35 \bool\_new:N \l\_\_cmd\_obey\_spaces\_bool

---

\l\_\_cmd\_last\_delimiters\_tl Holds the delimiters (first tokens) of all optional arguments since the previous mandatory argument, to warn about cases where it would be impossible to omit optional arguments completely because the following mandatory argument has the same delimiter as one of the optional arguments.

36 \tl\_new:N \l\_\_cmd\_last\_delimiters\_tl

---

\l\_\_cmd\_long\_bool Used to indicate that an argument is long, on a per-argument basis.

37 \bool\_new:N \l\_\_cmd\_long\_bool

---

\l\_\_cmd\_suppress\_strip\_bool

Used to indicate that an a pair of braces should not be stripped from an optional argument.

38 \bool\_new:N \l\_\_cmd\_suppress\_strip\_bool

---

\l\_\_cmd\_m\_args\_int The number of `m` arguments: if this is the same as the total number of arguments, then a short-cut can be taken in the creation of the grabber code.

39 \int\_new:N \l\_\_cmd\_m\_args\_int

---

\l\_\_cmd\_prefixed\_bool When preparing the signature of non-expandable commands, indicates that the current argument is affected by a processor or by + (namely is long).

40 \bool\_new:N \l\_\_cmd\_prefixed\_bool

---

\l\_\_cmd\_process\_all\_tl  
\l\_\_cmd\_process\_one\_tl  
\l\_\_cmd\_process\_some\_bool When preparing the signature, the processors that will be applied to a given argument are collected in \l\_\_cmd\_process\_one\_tl, while \l\_\_cmd\_process\_all\_tl contains processors for all arguments. The boolean indicates whether there are any processors (to bypass the whole endeavour otherwise).

41 \tl\_new:N \l\_\_cmd\_process\_all\_tl  
42 \tl\_new:N \l\_\_cmd\_process\_one\_tl  
43 \bool\_new:N \l\_\_cmd\_process\_some\_bool

---

\l\_\_cmd\_saved\_args\_tl Stores \l\_\_cmd\_args\_tl to deal with space-trimming of b-type arguments.

44 \tl\_new:N \l\_\_cmd\_saved\_args\_tl

---

\l\_\_cmd\_signature\_tl Used when constructing the signature (code for argument grabbing) to hold what will become the implementation of the main function. When arguments are grabbed (at point of use of the command/environment), it also stores the code for grabbing the remaining arguments.

45 \tl\_new:N \l\_\_cmd\_signature\_tl

---

\l\_\_cmd\_some\_obey\_spaces\_bool  
\l\_\_cmd\_some\_long\_bool  
\l\_\_cmd\_some\_short\_bool

These flags are set while normalizing the argument specification. The `obey_spaces` one is used to detect when ! is used on an argument that is not a trailing optional argument. The other two are used to check whether all short arguments appear before long arguments: this is needed to grab arguments expandably. As soon as the first long argument is seen (other than t-type, whose long status is ignored) the `some_long` flag is set. The `some_short` flag is used for expandable commands, to know whether to define a short auxiliary too.

46 \bool\_new:N \l\_\_cmd\_some\_obey\_spaces\_bool  
47 \bool\_new:N \l\_\_cmd\_some\_long\_bool  
48 \bool\_new:N \l\_\_cmd\_some\_short\_bool

---

\l\_\_cmd\_final\_verb\_bool Needed to establish whether optional arguments should be collected “verbatim safe”.

49 \bool\_new:N \l\_\_cmd\_final\_verb\_bool

---

```

\q__cmd_recursion_tail
\q__cmd_recursion_stop
\__cmd_use_i_delimit_by_q_recursion_stop:nw

```

Quarks and functions for internal processing.

```

50 \quark_new:N \q__cmd_recursion_tail
51 \quark_new:N \q__cmd_recursion_stop
52 \__kernel_quark_new_test:N \__cmd_if_recursion_tail_stop_do:Nn

```

(End of definition for \\_\_cmd\_if\_recursion\_tail\_stop\_do:Nn and  
\\_\_cmd\_use\_i\_delimit\_by\_q\_recursion\_stop:nw.)

---

```

\l__cmd_tmp_prop
\l__cmd_tmptl
\l__cmd_tmptl

```

Scratch space.

```

53 \prop_new:N \l__cmd_tmp_prop
54 \tl_new:N \l__cmd_tmptl
55 \tl_new:N \l__cmd_tmptl
56 \cs_new_eq:NN \__cmd_tmp:w ?

```

(End of definition for \\_\_cmd\_tmp:w.)

With `xparse`, information about commands being (re)defined was switched off by default, unless the `log-declarations` package option was used, so here we'll switch that off as well.

```

57 \msg_redirect_module:nnn { cmd } { info } { none }

```

Also add `cmd` to the LaTeX messages.

```

58 \prop_gput:Nnn \g_msg_module_type_prop { cmd } { LaTeX }

```

## 1.2 Declaring commands and environments

```

\__cmd_declare_cmd:Nnn
\__cmd_declare_expandable_cmd:Nnn
\__cmd_declare_cmd_aux:Nnn
\__cmd_declare_cmd_internal:Nnn

```

The main functions for creating commands set the appropriate flag then use the same internal code to do the definition.

```

59 \cs_new_protected:Npn \__cmd_declare_cmd:Nnn
60 {
61   \bool_set_false:N \l__cmd_expandable_bool
62   \__cmd_declare_cmd_aux:Nnn
63 }
64 \cs_new_protected:Npn \__cmd_declare_expandable_cmd:Nnn
65 {
66   \bool_set_true:N \l__cmd_expandable_bool
67   \__cmd_declare_cmd_aux:Nnn
68 }

```

The first stage is to log information, both for the user in the log and for programmatic use in a property list of all declared commands.

```

69 \cs_new_protected:Npn \__cmd_declare_cmd_aux:Nnn #1#2#3
70 {
71   \cs_if_exist:NTF #1
72   {
73     \msg_info:nnxx { cmd } { redefine }
74     { \token_to_str:N #1 } { \tl_to_str:n {#2} }
75   }
76   {
77     \bool_lazy_or:nnT
78     { \cs_if_exist_p:c { \cs_to_str:N #1 ~ code } }

```

```

79         { \cs_if_exist_p:c { \cs_to_str:N #1 ~ defaults } }
80     {
81         \msg_warning:nxx { cmd } { unsupported-let }
82         { \token_to_str:N #1 }
83     }
84     \msg_info:nxxx { cmd } { define-command }
85     { \token_to_str:N #1 } { \tl_to_str:n {#2} }
86 }
87 \bool_set_false:N \l__cmd_environment_bool
88 \__cmd_declare_cmd_internal:Nnnn #1 {#2} {#3} { }
89 }

```

At definition time, the variable `\l__cmd_fn_tl` is only used for error messages. The real business of defining a document command starts with setting up the appropriate name, then normalizing the argument specification to get rid of shorthands.

```

90 \cs_new_protected:Npn \__cmd_declare_cmd_internal:Nnnn #1#2#3#4
91 {
92     \tl_set:Nx \l__cmd_function_tl { \cs_to_str:N #1 }
93     \__cmd_normalize_arg_spec:n {#2}
94     \exp_args:No \__cmd_prepare_signature:n \l__cmd_arg_spec_tl
95     \__cmd_declare_cmd_code:Nnn #1 {#2} {#3}
96     #4
97     \__cmd_break_point:n {#2}
98 }

```

*(End of definition for `\__cmd_declare_cmd:Nnn` and others.)*

`\__cmd_break_point:n` A marker used to escape from creating a definition if necessary.

```

99 \cs_new_eq:NN \__cmd_break_point:n \use_none:n

```

*(End of definition for `\__cmd_break_point:n`.)*

`\__cmd_all_m_check:n` A quick loop to check for all (+)m-type arguments.

```

\__cmd_all_m_check_aux:n
100 \cs_new:Npn \__cmd_all_m_check:n #1
101 { \tl_map_function:nN {#1} \__cmd_all_m_check_aux:n }
102 \cs_new:Npn \__cmd_all_m_check_aux:n #1
103 {
104     \str_if_eq:nnF {#1} { m }
105     {
106         \str_if_eq:nnF {#1} { + }
107         { X }
108     }
109 }

```

*(End of definition for `\__cmd_all_m_check:n` and `\__cmd_all_m_check_aux:n`.)*

`\__cmd_declare_cmd_code:Nnn` At this stage we can check for a short-cut possibility: if the argument specification is made up of just (+)m tokens, and if all arguments are either short or long, then we can produce an optimized document command. This only applies to document commands, not creation of environments (which are more complex).

```

\__cmd_declare_cmd_optimized:Nnn
\__cmd_declare_cmd_code_aux:Nnn
\__cmd_declare_cmd_code_expandable:Nnn
\__cmd_start_optimized:
110 \cs_new_protected:Npn \__cmd_declare_cmd_code:Nnn #1#2
111 {
112     \bool_lazy_any:nTF
113     {
114         { \l__cmd_environment_bool }

```

```

115     {
116         \bool_lazy_and_p:nn
117         { \l__cmd_some_short_bool }
118         { \l__cmd_some_long_bool }
119     }
120     { ! \tl_if_blank_p:e { \__cmd_all_m_check:n {#2} } }
121 }
122 {
123     \tl_set:Nx \l__cmd_fn_tl
124     { \exp_not:c { \l__cmd_function_tl \c_space_tl } }
125     \bool_if:NTF \l__cmd_grab_expandably_bool
126     { \__cmd_declare_cmd_code_expandable:Nnn }
127     { \__cmd_declare_cmd_code_aux:Nnn }
128 }
129 { \__cmd_declare_cmd_optimized:Nnn }
130 #1 {#2}
131 }

```

The optimized version of commands just has to worry about whether to make them protected or long. The commands start with an expandable marker so that other parts of the kernel know these are set up by `ltxcmd`. We need the two layers of redirection so that the `code` internal function has the same form as it would for any other document command. Optimization means that there is no `\group_align_safe_begin:` before grabbing the arguments, so anything involving `&` tokens will not work. However, this is really only intended for making optional argument processing safe anyway, so in practice should not be an issue.

```

132 \cs_new_protected:Npn \__cmd_declare_cmd_optimized:Nnn #1#2#3
133 {
134     \bool_if:NTF \l__cmd_expandable_bool
135     { \cs_set_nopar:Npe }
136     { \cs_set_protected_nopar:Npe }
137     #1
138     {
139         \exp_not:N \__cmd_start_optimized:
140         \exp_not:c { \l__cmd_function_tl \c_space_tl code }
141     }
142     \exp_args:Ncc \cs_generate_from_arg_count:NNnn
143     { \l__cmd_function_tl \c_space_tl code }
144     {
145         cs_set
146         \bool_if:NF \l__cmd_expandable_bool { _protected }
147         \bool_if:NF \l__cmd_some_long_bool { _nopar }
148         :Npn
149     }
150     \l__cmd_current_arg_int
151     {#3}
152 }
153 \cs_new:Npn \__cmd_start_optimized: { }

```

Standard functions call `\__cmd_start:nNNnnn`, which receives the argument specification, an auxiliary used for grabbing arguments, an auxiliary containing the code, and then the signature, default arguments, and processors.

```

154 \cs_new_protected:Npn \__cmd_declare_cmd_code_aux:Nnn #1#2#3
155 {

```

```

156 \cs_generate_from_arg_count:cNnn
157 { \l__cmd_function_tl \c_space_tl code }
158 \cs_set_protected:Npn \l__cmd_current_arg_int {#3}
159 \cs_set_protected_nopar:Npx #1
160 {
161   \bool_if:NTF \l__cmd_environment_bool
162   {
163     \__cmd_start_env:nnnnn { \exp_not:n {#2} }
164     { \l__cmd_environment_str }
165   }
166   {
167     \__cmd_start:nNNnnn { \exp_not:n {#2} }
168     \exp_not:c { \l__cmd_function_tl \c_space_tl }
169     \exp_not:c { \l__cmd_function_tl \c_space_tl code }
170   }
171   { \exp_not:o \l__cmd_signature_tl }
172   {
173     \bool_if:NT \l__cmd_defaults_bool
174     { \exp_not:o \l__cmd_defaults_tl }
175   }
176   {
177     \bool_if:NT \l__cmd_process_some_bool
178     { \exp_not:o \l__cmd_process_all_tl }
179   }
180 }
181 }

```

Expandable functions and functions whose arguments can be grabbed expandably call `\__cmd_start_expandable:nNNNNn`, which receives the argument specification, four auxiliaries (two for grabbing arguments, one for the code, and one for default arguments), and finally the signature. Non-expandable functions that take this branch should nevertheless be protected, as well as their `code` function. They will only be expanded in contexts such as constructing a `csname`. The two grabbers (named after the function with one or two spaces) are needed when there are both short and long arguments; otherwise the same grabber is included twice in the definition. If all arguments are long or all are short the (only) grabber is defined correspondingly to be long/short. Otherwise two grabbers are defined, one long, one short.

```

182 \cs_new_protected:Npn \__cmd_declare_cmd_code_expandable:Nnn #1#2#3
183 {
184   \exp_args:Ncc \cs_generate_from_arg_count:NNnn
185   { \l__cmd_function_tl \c_space_tl code }
186   { \cs_set \bool_if:NF \l__cmd_expandable_bool { _protected } :Npn }
187   \l__cmd_current_arg_int {#3}
188   \bool_if:NT \l__cmd_defaults_bool
189   {
190     \use:x
191     {
192       \cs_generate_from_arg_count:cNnn
193       { \l__cmd_function_tl \c_space_tl defaults }
194       \cs_set:Npn \l__cmd_current_arg_int
195       { \exp_not:o \l__cmd_defaults_tl }
196     }
197   }
198   \bool_if:NTF \l__cmd_expandable_bool

```

```

199 { \cs_set_nopar:Npx } { \cs_set_protected_nopar:Npx } #1
200 {
201   \exp_not:N \l__cmd_start_expandable:nNNNNn

```

Creating a document environment requires a few more steps than creating a single command. In order to pass the arguments of the command to the end of the function, it is necessary to store the grabbed arguments. To do that, the function used at the end of the environment has to be redefined to contain the appropriate information. To minimize the amount of expansion at point of use, the code here is expanded now as well as when used. The last argument of `\__cmd_declare_cmd_internal:Nnnn` is only run if the definition succeeded. In package mode this ensures that the original definition of the environment is not changed if the definition fails for any reason. This also avoids an error when defining the `end_au_x` function when the user asks for more than 9 arguments.

### 1.3 Structure of xparse commands

`\__cmd_start_env:nnnnn`  
`\__cmd_start:nNNnnn`

For error messages that occur during run-time when getting arguments of environments it is necessary to keep track of the environment name. We begin non-expandable commands with a token equal to `\scan_stop:`, whose name gives a reasonable error message if the command is used inside a csname and protects against f-expansion. This is useless for environments since `\begin` is already not expandable. Both the command and environment codes start with `\group_align_safe_begin:`, then `\__cmd_run_code:` (used by both) does `\group_align_safe_end:`, so that delimited arguments may be grabbed in alignments if they contain an alignment tab token (see latex3/latex3/issues/839).

```

287 \cs_new_protected:Npn \__cmd_start_env:nnnnn #1#2
288 {
289   \conditionally@traceoff
290   \group_align_safe_begin:
291   \str_set:Nn \l__cmd_environment_str {#2}
292   \bool_set_true:N \l__cmd_environment_bool
293   \__cmd_start_aux:ccnnnn
294   { environment~ \l__cmd_environment_str \c_space_tl }
295   { environment~ \l__cmd_environment_str \c_space_tl code }
296   {#1}
297 }
298 \cs_new_protected:Npx \__cmd_start:nNNnnn #1#2#3
299 {
300   \exp_not:c { xparse~function~is~not~expandable }
301   \exp_not:N \conditionally@traceoff
302   \exp_not:N \group_align_safe_begin:
303   \exp_not:n { \bool_set_false:N \l__cmd_environment_bool }
304   \exp_not:N \__cmd_start_aux:NNnnnn
305   #2 #3 {#1}
306 }
```

(End of definition for `\__cmd_start_env:nnnnn` and `\__cmd_start:nNNnnn`.)

`\__cmd_start_aux:NNnnnn`  
`\__cmd_start_aux:ccnnnn`

This sets up a few variables to minimize the boilerplate code included in all xparse-defined commands. It then runs the grabbers #4. Again, the argument specification #1 is only for diagnostics.

```

307 \cs_new_protected:Npn \__cmd_start_aux:NNnnnn #1#2#3#4#5#6
308 {
309   \tl_clear:N \l__cmd_args_tl

323     { \exp_args:No \__cmd_set_environment_end:n \l__cmd_environment_str }
324   \group_align_safe_end:
325   \conditionally@traceon
326   \exp_after:wN \l__cmd_fn_code_tl \l__cmd_args_tl
327 }

```

(End of definition for \\_\_cmd\_run\_code:.)

\\_\_cmd\_defaults: First construct \\_\_cmd\_tmp:w (see below) that will receive the arguments found so far and determine default values for any missing argument. Then call it repeatedly until the set of arguments stabilizes. Since that could lead to an infinite loop we only call it up to nine times, the maximal number needed for stabilization if there is a chain of arguments that depend on each other. If that fails to stabilize raise an error.

```

\__cmd_defaults_def:nn
\__cmd_defaults_def:nnn
\__cmd_defaults_aux:
\__cmd_defaults_error:w
328 \cs_new_protected:Npn \__cmd_defaults:

396   { \exp_after:wN { \ProcessedArgument } }
397 }
398 \cs_new_protected:Npn \__cmd_args_process_aux:n #1
399 {
400   \cs_generate_from_arg_count:NNnn \__cmd_tmp:w \cs_set:Npn
401   { \tl_count:N \l__cmd_args_tl } {#1}
402   \exp_args:NNNo \exp_after:wN \__cmd_tmp:w \l__cmd_args_tl
403   { \ProcessedArgument }
404 }

```

(End of definition for `\__cmd_args_process:`, `\__cmd_args_process_loop:nn`, and `\__cmd_args_process_aux:n`.)

`\__cmd_start_expandable:nnNNNn`

This is called for all expandable commands. #6 is the signature, responsible for grabbing arguments. #5 is used to determine default values (or is ? if there are none). #4 is the code to run. #2 and #3 are functions (named after the command) that grab a single argument in the input stream (#3 is short). The argument specification #1 is only used by diagnostic functions. Same as for the non-expandable version, this starts with `\group_align_safe_begin:`, which expands to nothing, so may be safely used in an expandable context.

```
405 \cs_new:Npn \__cmd_start_expandable:nnNNNn #1#2#3#4#5#6
406 {
407   \group_align_safe_begin:
408   #6 \__cmd_end_expandable:NNw #5 #4 \q__cmd #2#3
409 }
```

(End of definition for `\__cmd_start_expandable:nnNNNn`.)

`\__cmd_end_expandable:NNw`

`\__cmd_end_expandable_aux:w`

`\__cmd_end_expandable_aux:nnNNN`

`\__cmd_end_expandable_defaults:nnnNNn`

`\__cmd_end_expandable_defaults:nnw`

`\__cmd_end_expandable_defaults:nn`

Followed by a function #1 to determine default values (or ? if there are no defaults), the code #2, arguments that have been grabbed, then `\q__cmd` and two generic grabbers. The idea to find default values is similar to the non-expandable case but we cannot define an auxiliary function, so at every step in the loop we need to go through all arguments searching for which ones started out as `-NoValue-` and replacing these by the newly computed values. In fact we need to keep track of three versions of all arguments: the original version, the previous version with default values, and the currently built version (first argument of `\__cmd_end_expandable_defaults:nnnNNn`).

```

## 1.4 Normalizing the argument specifications

The goal here is to expand aliases and check that the argument specification is valid before the main parsing run. If it is not valid the entire set up is abandoned to avoid any strange internal errors. A function is provided for each argument type that will grab any extra data items and call the loop function after performing the following checks and tasks.

- Check that each argument has the correct number of data items associated with it, and that where a single character is required, one has actually been supplied.
- Check that processors and the markers +, ! and = are followed by an argument for which they make sense, and are not redundant.
- Check the absence of forbidden types for expandable commands, namely G/v always, and l/u after optional arguments (xparse may have inserted braces due to a failed search for an optional argument).
- Check that no optional argument is followed by a mandatory argument with the same delimiter, as otherwise the optional argument could never be omitted.
- Keep track in \l\_\_cmd\_some\_long\_bool and \l\_\_cmd\_some\_short\_bool of whether the command has some long/short arguments.
- Keep track in \l\_\_cmd\_grab\_expandably\_bool of whether all arguments are m/l/u type and short arguments appear before long ones, in which case they can be grabbed expandably just as safely as they could be grabbed nonexpandably. Regardless of that, arguments of expandable commands will be grabbed expandably and arguments of environments will not (because the list of arguments built by non-expandable grabbing is used to pass them to the end-environment code).

Further checks happen at the end of the loop:

- that there are at most 9 arguments;
- that an expandable command does not end with an optional argument (this case is detected by using the fact that \l\_\_cmd\_last\_delimiters\_tl is cleared by every mandatory argument and filled by every optional argument).

```

__cmd_normalize_arg_spec:n Loop through the argument specification, calling an auxiliary specific to each argument
    __cmd_normalize_arg_spec_loop:n type. If any argument is unknown stop the definition.

\__cmd_normalize_type_D:w Optional argument types. Check that all required data is present (and consists of single
\__cmd_normalize_type_E:w characters if applicable) and check for forbidden types for expandable commands. For
\__cmd_normalize_type_t:w E-type require that there is at least one embellishment, that each one is a single character,
\__cmd_normalize_E_unique_check:w and that there aren't more optional arguments than embellishments; also remember that
each embellishment counts as one argument for \l__cmd_current_arg_int. Then in
each case store the data in \l__cmd_arg_spec_tl, and for later checks store in \l__-
cmd_last_delimiters_tl the tokens whose presence determines whether there is an
optional argument (for braces store {}, seen later as an empty delimiter).

(End of definition for \__cmd_single_token_check:n.)

```

`\__cmd_allowed_token_check:N` Some tokens are not allowed as delimiters for some argument types, notably implicit begin/end-group tokens (`\bgroup`/`\egroup`). The major problem with these tokens is that for `\peek_...` functions, a literal `{`<sub>1</sub> is virtually indistinguishable from a `\bgroup` or other token which was `\let` to a `{`<sub>1</sub>, and the same goes for `}`<sub>2</sub>. All other tokens can be easily distinguished from their implicit counterparts by grabbing them and looking at the string length (see `\__cmd_token_if_cs:NTF`), but for begin/end group tokens that is not possible without the risk of mistakenly grabbing the entire brace group (potentially leading to a ! Runaway argument error) or trying to grab a `}`<sub>2</sub>, leading to an ! Argument of `\dots` has an extra `}` error.

```

786         { an~optional~argument~before~mandatory~ \tl_to_str:n {'#1'} }
787     }
788     \__cmd_bad_def:wn
789   }
790   \tl_clear:N \l__cmd_last_delimiters_tl
791   \int_set_eq:NN \l__cmd_last_mandatory_arg_int \l__cmd_current_arg_int
792   \__cmd_add_arg_spec:n {#1}
793 }
```

(End of definition for `\__cmd_add_arg_spec:n` and `\__cmd_add_arg_spec_mandatory:n`.)

## 1.5 Preparing the signature: general mechanism

```
\__cmd_prepare_signature:n
\__cmd_prepare_signature_verb_chk:n
\__cmd_prepare_signature:N
\__cmd_prepare_signature_bypass:N
```

Actually creating the signature uses the same loop approach as normalizing the signature. There are first a number of variables which need to be set to track what is going on. Many of these variables are unused when defining expandable commands.

```
794 \cs_new_protected:Npn \__cmd_prepare_signature:n #1
795 {
796   \int_set_eq:NN \l__cmd_total_args_int \l__cmd_current_arg_int
797   \int_zero:N \l__cmd_current_arg_int
798   \bool_set_false:N \l__cmd_long_bool
799   \bool_set_false:N \l__cmd_obey_spaces_bool
800   \bool_set_false:N \l__cmd_suppress_strip_bool
801   \int_zero:N \l__cmd_m_args_int
802   \bool_set_false:N \l__cmd_defaults_bool
803   \tl_clear:N \l__cmd_defaults_tl
804   \tl_clear:N \l__cmd_process_all_tl
805   \tl_clear:N \l__cmd_process_one_tl
806   \bool_set_false:N \l__cmd_process_some_bool
807   \tl_clear:N \l__cmd_signature_tl
808   \__cmd_prepare_signature_verb_chk:n {#1}
809   \__cmd_prepare_signature:N #1 \q_recursion_tail \q_recursion_stop
810   \bool_if:NF \l__cmd_expandable_bool { \__cmd_flush_m_args: }
811 }
```

A quick check on the final arg. type.

```
812 \cs_new_protected:Npn \__cmd_prepare_signature_verb_chk:n #1
813 {
814   \str_if_eq:eeTF { \tl_head:e { \tl_reverse:n {#1} } } { c }
815   { \bool_set_true:N \l__cmd_final_verb_bool }
816   { \bool_set_false:N \l__cmd_final_verb_bool }
817 }
```

The main looping function does not take an argument, but carries out the reset on the processor boolean. This is split off from the rest of the process so that when actually setting up processors the flag-reset can be bypassed.

For each known argument type there is an appropriate function to actually do the addition to the signature. These are separate for expandable and standard functions, as the approaches are different.

```
818 \cs_new_protected:Npn \__cmd_prepare_signature:N
819 {
820   \bool_set_false:N \l__cmd_prefixed_bool
821   \__cmd_prepare_signature_bypass:N
822 }
823 \cs_new_protected:Npn \__cmd_prepare_signature_bypass:N #1
824 {
825   \quark_if_recursion_tail_stop:N #1
826   \use:c
827   {
828     __cmd_add
829     \bool_if:NT \l__cmd_grab_expandably_bool { _expandable }
830     _type_ \token_to_str:N #1 :w
831   }
```

```
832 }
```

(End of definition for `\__cmd_prepare_signature:n` and others.)

## 1.6 Setting up a standard signature

Each argument-adding function appends to the signature a grabber (and for some types, the delimiters or default value), except the one for `m` arguments. These are collected and added to the signature all at once by `\__cmd_flush_m_args:`, called for every other argument type. All of the functions then call the loop function `\__cmd_prepare_signature:N`. Default values of arguments are collected by `\__cmd_add_default:n` rather than being stored with the argument; this function and `\__cmd_add_default:` are also responsible for keeping track of `\l__cmd_current_arg_int`.

`\__cmd_add_type+:w` Making the next argument long means setting the flag. The `m` arguments are recorded here as this has to be done for every case where there is then a long argument.

```
833 \cs_new_protected:cpn { __cmd_add_type+:w }
834 {
835   \__cmd_flush_m_args:
836   \bool_set_true:N \l__cmd_long_bool
837   \bool_set_true:N \l__cmd_prefixed_bool
838   \__cmd_prepare_signature_bypass:N
839 }
```

(End of definition for `\__cmd_add_type+:w`.)

`\__cmd_add_type_!:w` Much the same for controlling trailing optional arguments.

```
840 \cs_new_protected:cpn { __cmd_add_type_!:w }
841 {
842   \__cmd_flush_m_args:
843   \bool_set_true:N \l__cmd_obey_spaces_bool
844   \bool_set_true:N \l__cmd_prefixed_bool
845   \__cmd_prepare_signature_bypass:N
846 }
```

(End of definition for `\__cmd_add_type_!:w`.)

`\__cmd_add_type_>:w` When a processor is found, the processor code is stored. It will be used by `\__cmd_args_process:` once arguments are all found. Here too the loop calls `\__cmd_prepare_signature_bypass:N` rather than `\__cmd_prepare_signature:N` so that the flag is not reset.

```
847 \cs_new_protected:cpn { __cmd_add_type_>:w } #1
848 {
849   \__cmd_flush_m_args:
850   \bool_set_true:N \l__cmd_prefixed_bool
851   \bool_set_true:N \l__cmd_process_some_bool
852   \tl_put_left:Nn \l__cmd_process_one_tl { {#1} }
853   \__cmd_prepare_signature_bypass:N
854 }
```

(End of definition for `\__cmd_add_type_>:w`.)

`\__cmd_add_type_=:w` A mix of the ideas from above: set a flag and add a processor.

```

855 \cs_new_protected:cpn { __cmd_add_type_=:w } #1
856 {
857   \__cmd_flush_m_args:
858   \bool_set_true:N \l__cmd_prefixed_bool
859   \bool_set_true:N \l__cmd_suppress_strip_bool
860   \bool_set_true:N \l__cmd_process_some_bool
861   \tl_put_left:Nn \l__cmd_process_one_tl
862     { { \__cmd_arg_to_keyvalue:nn {#1} } }
863   \__cmd_prepare_signature_bypass:N
864 }

```

*(End of definition for \\_\_cmd\_add\_type\_=:w.)*

```

\__cmd_add_type_b:w
\__cmd_add_type_c:w
\__cmd_add_type_b_or_c:N
865 \cs_new_protected:Npn \__cmd_add_type_b:w
866 { \__cmd_add_type_b_or_c:N b }
867 \cs_new_protected:Npn \__cmd_add_type_c:w
868 { \__cmd_add_type_b_or_c:N c }
869 \cs_new_protected:Npn \__cmd_add_type_b_or_c:N #1
870 {
871   \__cmd_flush_m_args:
872   \__cmd_add_default:
873   \__cmd_add_grabber:N #1
874   \__cmd_prepare_signature:N
875 }

```

*(End of definition for \\_\_cmd\_add\_type\_b:w, \\_\_cmd\_add\_type\_c:w, and \\_\_cmd\_add\_type\_b\_or\_c:N.)*

```

\__cmd_add_type_D:w
876 \cs_new_protected:Npn \__cmd_add_type_D:w #1#2#3
877 {
878   \__cmd_flush_m_args:
879   \__cmd_add_default:n {#3}
880   \__cmd_add_grabber:N D
881   \tl_put_right:Nn \l__cmd_signature_tl { #1 #2 }
882   \__cmd_prepare_signature:N
883 }

```

*(End of definition for \\_\_cmd\_add\_type\_D:w.)*

`\__cmd_add_type_E:w` The E-type argument needs a special handling of default values. Since each embellishment is a separate argument, it also needs to replicate the argument processors for each embellishment argument so that the numbers of arguments and processors remain in sync.

```

884 \cs_new_protected:Npn \__cmd_add_type_E:w #1#2
885 {
886   \__cmd_flush_m_args:
887   \__cmd_add_default_E:nn {#1} {#2}
888   \use:x
889   {
890     \__cmd_replicate_processor:nn { \tl_count:n {#1} }
891     { \exp_not:o \l__cmd_process_one_tl }
892   }

```

```

893 \__cmd_add_grabber:N E
894 \tl_put_right:Nn \l__cmd_signature_tl { {#1} }
895 \__cmd_prepare_signature:N
896 }

```

(End of definition for \\_\_cmd\_add\_type\_E:w.)

\\_\_cmd\_replicate\_processor:nn In the command's argument processor signature (the final argument of \\_\_cmd\_start:nnNnnn) there is one braced item for each formal argument (up to nine), and in each of these items there is one braced item for each processor (as many as there were processors declared for a given argument). Something like this:

```

{ % argument processors
  { % argument 1
    { processor 1 } { processor 2 } ... { processor n }
  } % end argument 1
  { ... } % argument 2
  :
  { ... } % argument n
} % end argument processors

```

The function \\_\_cmd\_add\_grabber:N adds one single grabber for an argument, and adds the braced item for that one argument. However, in an E-type argument each embellishment requires its own formal argument, so we need to break out of one layer of braces in \l\_\_cmd\_process\_one\_tl, add copies of the processor as necessary, and then return the removed brace. The function below does just that: it defines \l\_\_cmd\_process\_one\_tl starting with a }<sub>2</sub> and ending with a {<sub>1</sub>, so that it adds as many processors as needed when x-expanded.

```

897 \cs_new_protected:Npn \__cmd_replicate_processor:nn #1 #2
898 {
899   \int_compare:nNnF {#1} > { 1 } { \use_none:nnn }
900   \tl_set:Nx \l__cmd_process_one_tl
901   {
902     \exp_not:n { \exp_not:n {#2} \if_false: { \fi: } }
903     \prg_replicate:nn { #1 - 2 }
904     { \exp_not:n { \exp_not:n { {#2} } } }
905     \exp_not:n { { \if_false: } \fi: \exp_not:n {#2} }
906   }
907 }

```

(End of definition for \\_\_cmd\_replicate\_processor:nn.)

\\_\_cmd\_add\_type\_m:w The m type is special as short arguments which are not post-processed are simply counted at this stage. Thus there is a check to see if either of these cases apply. If so, a one-argument grabber is added to the signature. On the other hand, if a standard short argument is required it is simply counted at this stage, to be added later using \\_\_cmd\_flush\_m\_args:.

```

908 \cs_new_protected:Npn \__cmd_add_type_m:w
909 {
910   \__cmd_add_default:

```

```

911     \bool_if:NTF \l__cmd_prefixed_bool
912     { \__cmd_add_grabber:N m }
913     { \int_incr:N \l__cmd_m_args_int }
914     \__cmd_prepare_signature:N
915 }

```

*(End of definition for \\_\_cmd\_add\_type\_m:w.)*

\\_\_cmd\_add\_type\_R:w The R-type argument is very similar to the D-type.

```

916 \cs_new_protected:Npn \__cmd_add_type_R:w #1#2#3
917 {
918     \__cmd_flush_m_args:
919     \__cmd_add_default:n {#3}
920     \__cmd_add_grabber:N R
921     \tl_put_right:Nn \l__cmd_signature_tl { #1 #2 }
922     \__cmd_prepare_signature:N
923 }

```

*(End of definition for \\_\_cmd\_add\_type\_R:w.)*

\\_\_cmd\_add\_type\_t:w Setting up a t argument means collecting one token for the test, and adding it along with the grabber to the signature.

```

924 \cs_new_protected:Npn \__cmd_add_type_t:w #1
925 {
926     \__cmd_flush_m_args:
927     \__cmd_add_default:
928     \__cmd_add_grabber:N t
929     \tl_put_right:Nn \l__cmd_signature_tl {#1}
930     \__cmd_prepare_signature:N
931 }

```

*(End of definition for \\_\_cmd\_add\_type\_t:w.)*

\\_\_cmd\_add\_type\_v:w At this stage, the v argument is identical to l except that since the grabber may fail to read a verbatim argument we need a default value.

```

932 \cs_new_protected:Npn \__cmd_add_type_v:w
933 {
934     \__cmd_flush_m_args:
935     \exp_args:No \__cmd_add_default:n \c_novalue_tl
936     \__cmd_add_grabber:N v
937     \__cmd_prepare_signature:N
938 }

```

*(End of definition for \\_\_cmd\_add\_type\_v:w.)*

\\_\_cmd\_flush\_m\_args: As m arguments are simply counted, there is a need to add them to the token register in a block. As this function can only be called if something other than m turns up, the flag can be switched here.

```

939 \cs_new_protected:Npn \__cmd_flush_m_args:
940 {
941     \int_compare:nNnT \l__cmd_m_args_int > 0
942     {
943         \tl_put_right:Nx \l__cmd_signature_tl
944         { \exp_not:c { __cmd_grab_m_ \int_use:N \l__cmd_m_args_int :w } }
945         \tl_put_right:Nx \l__cmd_process_all_tl

```

```

946         { \prg_replicate:nn { \l__cmd_m_args_int } { { } } }
947     }
948     \int_zero:N \l__cmd_m_args_int
949 }

```

*(End of definition for \\_\_cmd\_flush\_m\_args:.)*

`\__cmd_add_grabber:N` To keep the various checks needed in one place, adding the grabber to the signature is done here. The only questions are whether the grabber should be long or not, and whether to obey spaces. The `\l__cmd_obey_spaces_bool` boolean can only be `true` for trailing optional arguments. In that case spaces will not be ignored when looking for that optional argument.

```

950 \cs_new_protected:Npn \__cmd_add_grabber:N #1
951 {
952     \tl_put_right:Nx \l__cmd_signature_tl
953     {
954         \exp_not:c
955         {
956             __cmd_grab_ #1
957             \bool_if:NT \l__cmd_long_bool { _long }
958             \bool_if:NT \l__cmd_obey_spaces_bool { _obey_spaces }
959             \bool_lazy_and:nnT
960             { \l__cmd_suppress_strip_bool }
961             { \str_if_eq_p:nn {#1} { D } }
962             { _no_strip }
963             \bool_lazy_all:nT
964             {
965                 { \l__cmd_final_verb_bool }
966                 { \str_if_eq_p:nn {#1} { D } }
967                 {
968                     \int_compare_p:nNn \l__cmd_current_arg_int
969                     > \l__cmd_last_mandatory_arg_int
970                 }
971             }
972             { _verb_safe }
973             :w
974         }
975     }
976     \bool_set_false:N \l__cmd_long_bool
977     \bool_set_false:N \l__cmd_obey_spaces_bool
978     \bool_set_false:N \l__cmd_suppress_strip_bool
979     \bool_set_false:N \l__cmd_verb_safe_bool
980     \tl_put_right:Nx \l__cmd_process_all_tl
981     {
982         {
983             \if_charcode:w E #1 \use_i:nn \fi:
984             \exp_not:o \l__cmd_process_one_tl
985         }
986     }
987     \tl_clear:N \l__cmd_process_one_tl
988 }

```

*(End of definition for \\_\_cmd\_add\_grabber:N.)*

`\__cmd_add_default:n` Store the default value of an argument, or rather code that gives that default value (it may involve other arguments). This is `\c_novalue_tl` for arguments with no actual default or with default `-NoValue-`; and (in a brace group) `\prg_do_nothing:` followed by a default value for others. For E-type arguments, pad the defaults #2 with some `\c_novalue_tl` until there are as many as embellishments #1. These functions are also used when defining expandable commands.

```

989 \cs_new_protected:Npn \__cmd_add_default:n #1
990 {
991   \tl_if_novalue:nTF {#1}
992     { \__cmd_add_default: }
993     {
994       \int_incr:N \l__cmd_current_arg_int
995       \bool_set_true:N \l__cmd_defaults_bool
996       \tl_put_right:Nn \l__cmd_defaults_tl { { \prg_do_nothing: #1 } }
997     }
998   }
999 \cs_new_protected:Npn \__cmd_add_default:
1000 {
1001   \int_incr:N \l__cmd_current_arg_int
1002   \tl_put_right:Nn \l__cmd_defaults_tl { \c_novalue_tl }
1003 }
1004 \cs_new_protected:Npn \__cmd_add_default_E:nn #1#2
1005 {
1006   \tl_map_function:nN {#2} \__cmd_add_default:n
1007   \prg_replicate:nn
1008     { \tl_count:n {#1} - \tl_count:n {#2} }
1009     { \__cmd_add_default: }
1010 }

```

(End of definition for `\__cmd_add_default:n`, `\__cmd_add_default:`, and `\__cmd_add_default_E:nn`.)

## 1.7 Setting up expandable types

The approach here is not dissimilar to that for standard types, but fewer types are supported. There is also a need to define the per-function auxiliaries: this is done here, while the general grabbers are dealt with later.

`\__cmd_add_expandable_type_+:w` We have already checked that short arguments are before long arguments, so `\l__cmd_long_bool` only changes from `false` to `true` once (and there is no need to reset it after each argument). Continue the loop.

```

1011 \cs_new_protected:cpn { __cmd_add_expandable_type_+ :w }
1012 {
1013   \bool_set_true:N \l__cmd_long_bool
1014   \__cmd_prepare_signature:N
1015 }

```

(End of definition for `\__cmd_add_expandable_type_+ :w`.)

`\__cmd_add_expandable_type_D:w` The set up for D-type arguments involves constructing a rather complex auxiliary which is used repeatedly when grabbing. There is an auxiliary here so that the R-type can share code readily: #1 is D or R. The `_aux:NN` auxiliary is needed if the two delimiting tokens are identical: in contrast to the non-expandable route, the grabber here has to act differently for this case.

```

1016 \cs_new_protected:Npn \__cmd_add_expandable_type_D:w
1017 { \__cmd_add_expandable_type_D_aux:NNNn D }
1018 \cs_new_protected:Npn \__cmd_add_expandable_type_D_aux:NNNn #1#2#3#4
1019 {
1020   \__cmd_add_default:n {#4}
1021   \tl_if_eq:nnTF {#2} {#3}
1022     { \__cmd_add_expandable_type_D_aux:NN #1 #2 }
1023     { \__cmd_add_expandable_type_D_aux:NNN #1 #2 #3 }
1024   \__cmd_prepare_signature:N
1025 }
1026 \cs_new_protected:Npn \__cmd_add_expandable_type_D_aux:NNN #1#2#3
1027 {
1028   \bool_if:NTF \l__cmd_long_bool
1029     { \cs_set:cpx }
1030     { \cs_set_nopar:cpx }
1031     { \l__cmd_expandable_aux_name_tl } ##1 ##2 #2 ##3 \q__cmd ##4 #3
1032     { ##1 {##2} {##3} {##4} }
1033   \__cmd_add_expandable_grabber:nn {#1}
1034   {
1035     \exp_not:c { \l__cmd_expandable_aux_name_tl }
1036     \exp_not:n { #2 #3 }
1037   }
1038 }
1039 \cs_new_protected:Npn \__cmd_add_expandable_type_D_aux:NN #1#2
1040 {
1041   \bool_if:NTF \l__cmd_long_bool
1042     { \cs_set:cpx }
1043     { \cs_set_nopar:cpx }
1044     { \l__cmd_expandable_aux_name_tl } ##1 #2 ##2 #2
1045     { ##1 {##2} }
1046   \__cmd_add_expandable_grabber:nn { #1_alt }
1047   {
1048     \exp_not:c { \l__cmd_expandable_aux_name_tl }
1049     \exp_not:n {#2}
1050   }
1051 }

```

(End of definition for \\_\_cmd\_add\_expandable\_type\_D:w and others.)

\\_\_cmd\_add\_expandable\_type\_E:w  
 \\_\_cmd\_add\_expandable\_type\_E\_aux:n

For each embellishment, use \\_\_cmd\_get\_grabber:NN to obtain an auxiliary delimited by that token and store a pair constituted of the auxiliary and the token in \l\_\_cmd\_tmpb\_tl, before appending the whole set of these pairs to the signature, and an equal number of -NoValue- markers (regardless of the default values of arguments). Set the current argument appropriately.

```

1052 \cs_new_protected:Npn \__cmd_add_expandable_type_E:w #1#2
1053 {

1069 {
1070     \__cmd_get_grabber:NN #1 \l__cmd_tmpa_tl
1071     \tl_put_right:Nx \l__cmd_tmpb_tl
1072     { \exp_not:o \l__cmd_tmpa_tl \exp_not:N #1 }
1073 }

```

(End of definition for \\_\_cmd\_add\_expandable\_type\_E:w and \\_\_cmd\_add\_expandable\_type\_E\_aux:n.)

\\_\_cmd\_add\_expandable\_type\_m:w Unlike the standard case, when working expandably each argument is always grabbed separately.

```

1074 \cs_new_protected:Npn \__cmd_add_expandable_type_m:w
1075 {
1076     \__cmd_add_default:
1077     \__cmd_add_expandable_grabber:nn
1078     { m \bool_if:NT \l__cmd_long_bool { _long } } { }
1079     \__cmd_prepare_signature:N
1080 }

```

(End of definition for \\_\_cmd\_add\_expandable\_type\_m:w.)

\\_\_cmd\_add\_expandable\_type\_R:w The R-type is very similar to the D-type argument, and so the same internals are used.

```

1081 \cs_new_protected:Npn \__cmd_add_expandable_type_R:w
1082 { \__cmd_add_expandable_type_D_aux:NNNn R }

```

(End of definition for \\_\_cmd\_add\_expandable\_type\_R:w.)

\\_\_cmd\_add\_expandable\_type\_t:w An auxiliary delimited by #1 is built now. It will be used to test for the presence of that token.

```

1083 \cs_new_protected:Npn \__cmd_add_expandable_type_t:w #1
1084 {
1085     \__cmd_add_default:
1086     \__cmd_get_grabber:NN #1 \l__cmd_tmpa_tl
1087     \__cmd_add_expandable_grabber:nn { t }
1088     {

1091     }
1092     \__cmd_prepare_signature:N
1093 }

```

(End of definition for \\_\_cmd\_add\_expandable\_type\_t:w.)

\\_\_cmd\_add\_expandable\_grabber:nn This is called for all arguments to place the right grabber in the signature.

```

1094 \cs_new_protected:Npn \__cmd_add_expandable_grabber:nn #1#2
1095 {
1096     \tl_put_right:Nx \l__cmd_signature_tl
1097     { \exp_not:c { __cmd_expandable_grab_ #1 :w } #2 }
1098 }

```

(End of definition for `\__cmd_add_expandable_grabber:nn`.)

`\__cmd_get_grabber:NN`  
`\__cmd_get_grabber_auxi:NN`  
`\__cmd_get_grabber_auxii:NN`

Given a token #1, defines an expandable function delimited by that token and stores it in the token list #2. The function is named after the token, unless that function name is already taken by some other grabber (this can happen in the rare case where delimiters with different category codes are used in the same document): in that case use a global counter to get a unique name. Since the grabbers are not named after `xparse` commands they should not be used to get material from the input stream.

```

### 1.7.1 Copying a command and its internal structure

```

1128 <latexrelease>\IncludeInRelease{2021/11/15}{\__cmd_copy:NN}%
1129 <latexrelease> {Support~\NewCommandCopy~in~ltxcmd}

```

Since the 2020-10-01 L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> release, support for copying, and showing the definition of, robust commands has been available, but the specifics of each command are implemented separately. Here we'll add support for copying and showing `ltxcmd` definitions.

To fully support copying, we need two commands: a conditional to test if a command is in fact a `ltxcmd` command, and another command to actually copy the command. The conditional is defined later as `\__kernel_cmd_if_xparse:NTF`, so now to the copying:

`\__cmd_copy:NN` This macro just branches to the proper copying command by using `\__cmd_cmd_type_cases:NnnnnnF`. The copying command takes the names of the commands to be copied to and from, and the actual commands as its four arguments.

```

1130 \cs_new_protected:Npn \__cmd_copy:NN #1 #2
1131 {
1132   \use:x
1133   {
1134     \int_set:Nn \tex_escapechar:D { 92 }
1135     \exp_not:N \__cmd_cmd_type_cases:NnnnnnF \exp_not:N #2
1136     { \__cmd_copy_command:nnNN }
1137     { \__cmd_copy_expandable:nnNN }
1138     { \__cmd_copy_optimized:nnNN }
1139     { \__cmd_copy_environment:nnNN }
1140     { \__cmd_copy_environment_end:nnNN }
1141     { \__cmd_cant_copy:nwn { non-ltcmd } }
1142     { \cs_to_str:N #1 } { \cs_to_str:N #2 }
1143     \exp_not:N #1 \exp_not:N #2
1144     \exp_not:N \__cmd_break_point:n { \cs_to_str:N #2 }
1145     \int_set:Nn \tex_escapechar:D { \int_use:N \tex_escapechar:D }
1146   }
1147 }
1148 \cs_new_protected:Npn \__cmd_set_eq_if_exist:NN #1 #2
1149 { \cs_if_exist:NTF #2 { \cs_set_eq:NN } { \use_none:nn } #1 #2 }
1150 \cs_generate_variant:Nn \__cmd_set_eq_if_exist:NN { cc }

```

An utility macro similar to `\__cmd_bad_def:wn` to abort a command copy. Contrary to `\__cmd_bad_def:wn` though, when this happens the issue is most likely internal, because the command was already (supposedly) correctly defined so it should be copyable. Hopefully this macro will never be used ever, but if it does, apologise and give the reason for the failure so the user can report.

```

1151 \cs_new_protected:Npn \__cmd_cant_copy:nwn #1 #2 \__cmd_break_point:n #3
1152 { \msg_error:nnnn { cmd } { copy-bug } {#1} {#3} }
1153 \msg_new:nnn { cmd } { copy-bug }
1154 {
1155   Error~while~copying~command~\iow_char:N\#2:\
1156   \str_case:nn {#1}
1157   {
1158     { non-ltcmd } { Command~is~not~a~valid~ltcmd~command. }
1159     { unknown-type } { Found~an~unknown~argument~type. }
1160     { invalid-end }
1161     { Target~command~is~not~named~\iow_char:N \end<name>. }
1162   }
1163 }

```

And, of course, add `\__kernel_cmd_if_xparse:NTF` and `\__cmd_copy:NN` to `\@declarecommandcopylisthook`:

```

1164 \tl_gput_right:Nn \@declarecommandcopylisthook
1165 { { \__kernel_cmd_if_xparse:NTF \__cmd_copy:NN } }

```

(End of definition for `\__cmd_copy:NN`, `\__cmd_set_eq_if_exist:NN`, and `\__cmd_cant_copy:nwn`.)

`\__cmd_copy_command:nnNN` A normal (non-expandable) command has a pretty straightforward structure. Its definition is stored in `\<cmd>_code`, its defaults (if any) are stored in `\<cmd>_defaults`, and its

top-level definition contains its signature, which can just be copied over. `\__cmd_copy_command:nnNN` copies the command code and defaults, and then defines the top-level command using the auxiliary `\__cmd_copy_command:NnNNnnnn`. This macro takes the signature of the command being copied from its top-level definition, and replaces the named bits with the new name.

```

1166 \cs_new_protected:Npn \__cmd_copy_command:nnNN #1 #2 #3 #4
1167 {
1168   \cs_set_eq:cc { #1 ~ code } { #2 ~ code }
1169   \__cmd_set_eq_if_exist:cc { #1 ~ defaults } { #2 ~ defaults }
1170   \cs_set_protected_nopar:Npx #3
1171   { \exp_after:wN \__cmd_copy_command:NnNNnnnn #4 {#1} }
1172 }
1173 \cs_new:Npn \__cmd_copy_command:NnNNnnnn #1 #2 #3 #4 #5 #6 #7 #8
1174 {
1175   #1 \exp_not:n { {#2} }
1176   \exp_not:c { #8 ~ } \exp_not:c { #8 ~ code }
1177   \exp_not:n { {#5} {#6} {#7} }
1178 }

```

(End of definition for `\__cmd_copy_command:nnNN` and `\__cmd_copy_command:NnNNnnnn`.)

```

\__cmd_copy_expandable:nnNN
\__cmd_copy_expandable:NnNNNNnnn

```

An expandable command is slightly more complicated. Besides the `\<cmd>_code`, and `\<cmd>_defaults`, it also has an auxiliary `\<cmd>_l` for grabbing delimited arguments, and possibly another auxiliary `\<cmd>_ll`, if the command has both long and short arguments. Then, its signature also has several specific bits that are unique to that command; this is in contrast to non-expandable commands, which use a common set of parsing functions.

We start by copying the basics, then call `\__cmd_copy_expandable_signature:NnNNNNnnnn` to parse the signature of the command and build up the modified copy in a temporary token list, then we call `\__cmd_copy_expandable:NnNNNNnnnn` that will copy the top-level definition of the command, with the proper internal renames.

```

1179 <latexrelease> \EndIncludeInRelease
1180 <latexrelease> \IncludeInRelease{2020/10/01}{\__cmd_copy:NN}%
1181 <latexrelease> {Support~\NewCommandCopy~in~ltxcmd}
1182 <latexrelease> \EndIncludeInRelease

```

There's one variant: a command begins with `\__cmd_start_expandable:nNNNNn` may still be un-expandable/protected if it's defined by `\NewDocumentCommand` and friends, with empty or only m-type arguments.

```

1254   {
1255     \quark_if_recursion_tail_stop:n {#3}
1256     \int_incr:N \l__cmd_current_arg_int
1257     \exp_after:wN \__cmd_copy_parse_grabber:w \token_to_str:N #3 {#1} {#2}
1258   }
1259 \use:x
1260   {
1261     \cs_new_protected:Npn \exp_not:N \__cmd_copy_parse_grabber:w ##1
1262       \tl_to_str:n { expandable_grab_ } ##2 \tl_to_str:n { :w }
1263       {
1264         \tl_put_right:Nx \exp_not:N \l__cmd_tmpa_tl
1265           { \exp_not:N \exp_not:c { __cmd_expandable_grab_##2:w } }
1266         \exp_not:N \cs_if_exist_use:cF { __cmd_copy_grabber_##2:w }
1267           { \__cmd_cant_copy:nwn { unknown-type } }
1268       }
1269   }

```

The most complicated is the Delimited argument: each argument has a dedicated grabbing function named after the command that has to be copied over (of the form  $\backslash\langle cmd \rangle_{\square}(\arg_{\square}\langle num \rangle)$ ).

```

1270 \cs_new_protected:Npn \__cmd_copy_grabber_D:w #1 #2 #3 #4 #5
1271   {
1272     \tl_put_right:Nx \l__cmd_tmpa_tl
1273     {
1274       \exp_not:c { #1 ~ (arg ~ \int_use:N \l__cmd_current_arg_int ) }
1275       \exp_not:n { #4 #5 }
1276     }
1277     \cs_set_eq:cc
1278       { #1 ~ (arg ~ \int_use:N \l__cmd_current_arg_int ) }
1279       { #2 ~ (arg ~ \int_use:N \l__cmd_current_arg_int ) }
1280     \__cmd_copy_expandable:nnN {#1} {#2}
1281   }

```

`\__cmd_copy_grabber_D:w`  
`\__cmd_copy_grabber_D_alt:w`  
`\__cmd_copy_grabber_R:w`  
`\__cmd_copy_grabber_R_alt:w`  
`\__cmd_copy_grabber_E:w`  
`\__cmd_copy_grabber_E_long:w`  
`\__cmd_copy_grabber_t:w`  
`\__cmd_copy_grabber_m:w`  
`\__cmd_copy_grabber_m_long:w`

`D_alt` is just a special case of `D` that uses a single delimiter (used when both delimiters of the argument are identical):

```

1282 \cs_new_protected:Npn \__cmd_copy_grabber_D_alt:w #1 #2 #3 #4
1283   { \__cmd_copy_grabber_D:w {#1} {#2} {#3} {#4} { } }

```

As far as copying is concerned, `R` is identical to `D`:

```

1284 \cs_new_eq:NN \__cmd_copy_grabber_R:w \__cmd_copy_grabber_D:w
1285 \cs_new_eq:NN \__cmd_copy_grabber_R_alt:w \__cmd_copy_grabber_D_alt:w

```

E is straightforward: we just copy the embellishments over, and increase the current argument number `\l__cmd_current_arg_int` by the number of embellishments (minus one because there is a `\int_incr:N` down the line).

```

1286 \cs_new_protected:Npn \__cmd_copy_grabber_E:w #1 #2 #3 #4
1287 {
1288   \tl_put_right:Nn \l__cmd_tmpa_tl { {#3} {#4} }
1289   \int_add:Nn \l__cmd_current_arg_int { \tl_count:n {#4} - 1 }
1290   \__cmd_copy_expandable:nnN {#1} {#2}
1291 }
1292 \cs_new_eq:NN \__cmd_copy_grabber_E_long:w \__cmd_copy_grabber_E:w
    t just needs copying the token to be tested for:
1293 \cs_new_protected:Npn \__cmd_copy_grabber_t:w #1 #2 #3 #4
1294 {
1295   \tl_put_right:Nn \l__cmd_tmpa_tl { #3 #4 }
1296   \__cmd_copy_expandable:nnN {#1} {#2}
1297 }

```

And last but not least, `m` is the simplest; the grabber is just `\__cmd_expandable_grab_m:w`, which is already added to the new command so here we just resume the loop:

```

1298 \cs_new_protected:Npn \__cmd_copy_grabber_m:w { \__cmd_copy_expandable:nnN }
1299 \cs_new_eq:NN \__cmd_copy_grabber_m_long:w \__cmd_copy_grabber_m:w

```

*(End of definition for `\__cmd_copy_expandable:nnNN` and others.)*

`\__cmd_copy_environment:nnNN` Copying an environment's `\begin` part is pretty much like copying a command, except it has a longer name, and at the end we have to copy `\environment <name>` into `\<name>`.

```

1300 \cs_new_protected:Npn \__cmd_copy_environment:nnNN #1 #2 #3 #4
1301 {
1302   \cs_set_eq:cc { environment~ #1 ~ code } { environment~ #2 ~ code }
1303   \__cmd_set_eq_if_exist:cc
1304     { environment~ #1 ~ defaults } { environment~ #2 ~ defaults }
1305   \cs_set_protected_nopar:cpx { environment~ #1 }
1306     { \exp_after:wN \__cmd_copy_environment:Nnnnnnn #4 {#1} }
1307   \cs_set_eq:cc {#1} { environment~ #1 }
1308 }
1309 \cs_new:Npn \__cmd_copy_environment:Nnnnnnn #1 #2 #3 #4 #5 #6 #7
1310 { #1 \exp_not:n { {#2} } {#7} \exp_not:n { {#4} {#5} {#6} } }

```

*(End of definition for `\__cmd_copy_environment:nnNN` and `\__cmd_copy_environment:Nnnnnnn`.)*

`\__cmd_copy_environment_end:nnNN` Copying an environment's `\end` part is a bit trickier. We first have to make sure that both parts are named `\end<name>` (that's actually not a hard requirement, but an environment `\end` command makes no sense without the `end` in its name), and strip the leading `end` from the strings. After that, copying is straightforward.

```

1311 \cs_new_protected:Npn \__cmd_copy_environment_end:nnNN #1 #2
1312 {
1313   \__cmd_check_end:Nn \l__cmd_tmpa_tl {#1}
1314   \__cmd_check_end:Nn \l__cmd_tmpb_tl {#2}
1315   \exp_args:Noo \__cmd_copy_environment_end_aux:nnNN
1316     { \l__cmd_tmpa_tl } { \l__cmd_tmpb_tl }
1317 }
1318 \cs_new_protected:Npn \__cmd_copy_environment_end_aux:nnNN #1 #2 #3 #4
1319 {

```

```

1320 \cs_set_nopar:cpx { environment~ #1 ~end }
1321 { \exp_not:c { environment~ #1 ~end~aux } }
1322 \cs_set_eq:cc
1323 { environment~ #1 ~end~aux~ } { environment~ #2 ~end~aux~ }
1324 \cs_set_eq:cc { end #1 } { environment~ #1 ~end }
1325 }

```

To check whether an `\end` command is valid, we look for the string `end` at the beginning of the command name, and if not found, raise an error:

```

\__cmd_check_end:Nn 1326 \cs_new_protected:Npn \__cmd_check_end:Nn #1 #2
\__cmd_check_end:n 1327 {
\__cmd_check_end:w 1328 \tl_set:Nx #1 { \__cmd_check_end:n {#2} }
1329 \token_if_eq_meaning:NNT #1 \q_nil
1330 { \__cmd_cant_copy:nwn { invalid-end } }
1331 }
1332 \cs_set_protected:Npn \__cmd_tmp:w #1
1333 {
1334 \cs_new:Npn \__cmd_check_end:n ##1
1335 {
1336 \exp_after:wN \__cmd_check_end:w \tl_to_str:n {##1}
1337 #1 \q_mark #1 \q_stop
1338 }
1339 \cs_new:Npn \__cmd_check_end:w ##1 #1 ##2 #1 ##3 \q_stop
1340 { \if_meaning:w ##2 \q_mark \exp_not:N \q_nil \else: ##2 \fi: }
1341 }
1342 \exp_args:No \__cmd_tmp:w { \tl_to_str:n { end } }

```

(End of definition for `\__cmd_copy_environment_end:nnNN` and others.)

Not much to do regarding `latexrelease`: we could remove the entries from `\@declarecommandcopylist` but it doesn't seem worth it.

```

1343 <latexrelease> \EndIncludeInRelease
1344 <latexrelease> \IncludeInRelease{2020/10/01}{\__cmd_copy:NN (part 2)}%
1345 <latexrelease> {Support~\NewCommandCopy~in~ltxcmd}
1346 <latexrelease> \EndIncludeInRelease

```

## 1.7.2 Showing the definition of a command

```

1347 <latexrelease> \IncludeInRelease{2021/11/15}{\__cmd_show:N}%
1348 <latexrelease> {Support~\ShowCommand~in~ltxcmd}

```

To show the definition of a command we need more or less the same building blocks as for copying, except that instead of making a copy, we'll just print stuff to the terminal.

`\__cmd_show:N` This macro just branches to the proper showing command by using `\__cmd_cmd_type_cases:NnnnnnF`. The showing command takes the command to be shown as argument.

```

1349 \cs_new_protected:Npn \__cmd_show:N #1
1350 {
1351 \use:x
1352 {
1353 \int_set:Nn \tex_escapechar:D { 92 }
1354 \exp_not:N \__cmd_cmd_type_cases:NnnnnnF \exp_not:N #1
1355 { \__cmd_show_command:N }
1356 { \__cmd_show_expandable:N }
1357 { \__cmd_show_optimized:N }
1358 { \__cmd_show_environment:N }

```

```

1359         { \_cmd_show_environment_end:N }
1360         { \_cmd_cant_copy:nwn { non-ltcmd } }
1361         \exp_not:N #1
1362         \exp_not:N \_cmd_break_point:n { \cs_to_str:N #1 }
1363         \int_set:Nn \tex_escapechar:D { \int_use:N \tex_escapechar:D }
1364     }
1365 }

```

(End of definition for \\_cmd\_show:N.)

\\_cmd\_show\_command:N These commands just expand the command once to reveal its innards, then pass the type of command, the control sequence, the signature, and the code macro to \\_cmd\_show\_command\_aux:NnNNn.

```

1366 \cs_new_protected:Npn \_cmd_show_command:N #1
1367 { \exp_after:wN \_cmd_show_command:NnNNwN #1 \q_cmd #1 }
1368 \cs_new_protected:Npn \_cmd_show_command:NnNNwN #1 #2 #3 #4 #5 \q_cmd #6
1369 {
1370     \_cmd_show_command_aux:NnNNn \tl_show:x
1371     { document~command } #6 #4 {#2}
1372 }
1373 \cs_new_protected:Npn \_cmd_show_expandable:N #1
1374 { \exp_after:wN \_cmd_show_expandable:NnNNNNnN #1 #1 }
1375 <latexrelease>\EndIncludeInRelease
1376 <latexrelease>\IncludeInRelease{2020/10/01}{\_cmd_show:N}%
1377 <latexrelease> {Support~\ShowCommand~in~ltcmd}
1378 <latexrelease>\EndIncludeInRelease

```

There's one variant: a command begins with \\_cmd\_start\_expandable:nNNNNn may still be un-expandable/protected if it's defined by \NewDocumentCommand and friends, with empty or only m-type arguments.

```

1379 <latexrelease>\IncludeInRelease{2023/06/01}{\_cmd_show_expandable:NnNNNNnN}%
1380 <latexrelease> {Distinguish~non~expandable~document~commands}
1381 \cs_new_protected:Npn \_cmd_show_expandable:NnNNNNnN #1 #2 #3 #4 #5 #6 #7 #8
1382 {
1383     \exp_args:NNe \_cmd_show_command_aux:NnNNn \tl_show:x
1384     { \token_if_protected_macro:NF #8 { expandable~ } document~command }
1385     #8 #5 {#2}
1386 }
1387 <latexrelease>\EndIncludeInRelease
1388 <latexrelease>\IncludeInRelease{2021/11/15}{\_cmd_show_expandable:NnNNNNnN}%
1389 <latexrelease> {Support~\ShowCommand~in~ltcmd}
1390 <latexrelease>\cs_new_protected:Npn \_cmd_show_expandable:NnNNNNnN #1 #2 #3 #4 #5 #6 #7 #8
1391 <latexrelease> {
1392     \_cmd_show_command_aux:NnNNn \tl_show:x
1393     { expandable~document~command } #8 #5 {#2}
1394 }
1395 <latexrelease>\EndIncludeInRelease
1396 <latexrelease>\IncludeInRelease{2020/10/01}{\_cmd_show_expandable:NnNNNNnN}%
1397 <latexrelease> {Support~\ShowCommand~in~ltcmd}
1398 <latexrelease>\EndIncludeInRelease
1399 <latexrelease>\IncludeInRelease{2021/11/15}{\_cmd_show:N (part 2)}%
1400 <latexrelease> {Support~\ShowCommand~in~ltcmd}

```

Now just print everything in the required format. The auxiliary `\__cmd_split_signature:n` stores a ready-to-print token list in `\l__cmd_tmpa_tl`, so we use that here:

```

1401 \cs_new_protected:Npn \__cmd_show_command_aux:NnNnNn #1 #2 #3 #4 #5
1402 {
1403   \__cmd_split_signature:n {#5}
1404   #1
1405   {
1406     \token_to_str:N #3 = #2: \iow_newline:
1407     \tl_use:N \l__cmd_tmpa_tl
1408     -> \cs_replacement_spec:N #4
1409   }
1410 }

```

Optimized functions need things done a bit differently as we need to reconstruct the argument spec.

```

1411 \cs_new_protected:Npn \__cmd_show_optimized:N #1
1412 {
1413   \exp_args:Nc \__cmd_show_optimized:NN
1414   { \cs_to_str:N #1 \c_space_tl code }
1415   #1
1416 }
1417 \cs_new_protected:Npn \__cmd_show_optimized:NN #1#2
1418 {
1419   \cs_set:Npe \__cmd_show_optimized_aux:N ##1
1420   {
1421     \c_space_tl \c_space_tl \c_hash_str ##1 :
1422     \bool_lazy_or:nnT
1423     { \token_if_long_macro_p:N #1 }
1424     { \token_if_protected_long_macro_p:N #1 }
1425     { + } m
1426     \iow_newline:
1427   }
1428   \tl_show:e
1429   {
1430     \token_to_str:N #2 =
1431     \bool_lazy_or:nnF
1432     { \token_if_protected_macro_p:N #1 }
1433     { \token_if_protected_long_macro_p:N #1 }
1434     { expandable ~ } document-command:
1435     \iow_newline:
1436     \int_step_function:nN
1437     {
1438       \int_div_truncate:nn
1439       { \tl_count:e { \cs_parameter_spec:N #1 } }
1440       { 2 }
1441     }
1442     \__cmd_show_optimized_aux:N
1443     ->
1444     \cs_replacement_spec:N #1
1445   }
1446 }
1447 \cs_generate_variant:Nn \tl_count:n { e }

```

We can reuse most of the above to show an environment, except that we need to ensure that the proper `\environment ...` are passed to `\__cmd_show_command_aux:NnnNn`. Additionally, when `\ShowCommand\foo` is used (if `foo` is an environment), we show `\endfoo` as well, and when `\ShowCommand\endfoo` is used, change that to `\ShowCommand\foo` and do the same.

```

1448 \cs_new_protected:Npn \__cmd_show_environment:N #1
1449 {
1450   \exp_after:wN \__cmd_show_environment:Nnnw #1 \q__cmd
1451   \tl_show:x
1452   {
1453     \token_to_str:N \end { \cs_to_str:N #1 } : \iow_newline:
1454     -> \exp_args:Nc \cs_replacement_spec:N
1455       { environment~ \cs_to_str:N #1 ~end~aux~ }
1456   }
1457 }
1458 \cs_new_protected:Npn \__cmd_show_environment:Nnnw #1 #2 #3 #4 \q__cmd
1459 {
1460   \use:x
1461   {
1462     \__cmd_show_command_aux:NnnNn \__cmd_show:x { document~environment }
1463     { \exp_not:N \begin {#3} }
1464     \exp_not:c { environment~ #3 ~ code }
1465     {#2}
1466   }
1467 }
1468 \cs_if_exist:NTF \iow_show:e
1469 {
1470   \cs_new_protected:Npn \__cmd_show:x #1
1471   { \iow_show:e { > ~ #1 . \iow_newline: } }
1472 }
1473 {
1474   \cs_new_protected:Npn \__cmd_show:x #1
1475   { \iow_term:x { > ~ #1 . \iow_newline: } }
1476 }
1477 \cs_new_protected:Npn \__cmd_show_environment_end:N #1
1478 {
1479   \exp_args:NNx \__cmd_check_end:Nn \l__cmd_tmpa_tl { \cs_to_str:N #1 }
1480   \exp_args:Nc \__cmd_show_environment:N { \l__cmd_tmpa_tl }
1481 }

```

And, of course, add `\__kernel_cmd_if_xparse:NTF` and `\__cmd_show:N` to `\@showcommandlisthook` and to `\@showenvironmentlisthook` (`\__cmd_show:N` takes care of the environment case as well, so both entries are identical):

```

1482 \tl_gput_right:Nn \@showcommandlisthook
1483 { { \__kernel_cmd_if_xparse:NTF \__cmd_show:N } }
1484 \tl_gput_right:Nn \@showenvironmentlisthook
1485 { { \__kernel_cmd_if_xparse:NTF \__cmd_show:N } }

```

*(End of definition for `\__cmd_show_command:N` and others.)*

`\__cmd_split_signature:n` Now we'll try a least-effort adventure into splitting the symbolic user-provided signature for a command into individual parameters for pretty-printing. A counter is used to keep track of the current argument number, and two token lists are used: `\l__cmd_tmpa_tl` holds the final token list to be printed, and `\l__cmd_tmpb_tl` holds just the current item,

so that we can make changes to an individual item without having to dissect the whole thing (this is used for e- and E-types).

```

1486 \cs_new_protected:Npn \__cmd_split_signature:n #1
1487 {
1488   \int_set:Nn \l__cmd_current_arg_int { 1 }
1489   \tl_clear:N \l__cmd_tmpa_tl
1490   \tl_clear:N \l__cmd_tmpb_tl
1491   \__cmd_split_signature_loop:Nw #1 \q_recursion_tail \q_recursion_stop
1492 }

```

\\_\_cmd\_split\_signature\_loop:Nw This is the main chunk of the loop: it starts an item with \\_\_cmd\_split\_start\_item: (this adds indentation and the argument number to \l\_\_cmd\_tmpb\_tl), then checks if a special token list \c\_\_cmd\_show\_type\_⟨type⟩\_tl exists. If it doesn't, the current argument is a “simple” type which needs no extra processing. Otherwise, call a specific function depending on the value of said token list.

```

1493 \cs_new_protected:Npn \__cmd_split_signature_loop:Nw #1
1494 {
1495   \quark_if_recursion_tail_stop:N #1
1496   \tl_if_empty:NT \l__cmd_tmpb_tl { \__cmd_split_start_item: }
1497   \tl_if_exist:cTF { c__cmd_show_type_#1_tl }
1498   {
1499     \use:c
1500     {
1501       __cmd_show_
1502       \if_case:w \tl_use:c { c__cmd_show_type_#1_tl } \exp_stop_f:
1503       delim \or: delims \or: delims_opt \or: opt \or:
1504       e \or: E \or: prefix \or: processor \fi: :Nw
1505     } #1
1506   }
1507   { \__cmd_split_end_item:n {#1} \__cmd_split_signature_loop:Nw }
1508 }

```

The token lists \c\_\_cmd\_show\_type\_⟨type⟩\_tl exist for nontrivial (for printing) ⟨types⟩ that require special parsing (like delimiters or optional arguments). Values from 0 to 7 are assigned to each type:

```

\c__cmd_show_type_t_tl
\c__cmd_show_type_r_tl
\c__cmd_show_type_d_tl
\c__cmd_show_type_R_tl
\c__cmd_show_type_D_tl
\c__cmd_show_type_0_tl
\c__cmd_show_type_e_tl
\c__cmd_show_type_E_tl
\c__cmd_show_type+_tl
\c__cmd_show_type!_tl
\c__cmd_show_type>_tl

```

1. a single delimiter token;
2. two delimiter tokens;
3. two delimiter tokens plus a default value;
4. a default value;
5. a list of embellishments (exclusive for e-type);
6. embellishments plus defaults (exclusive for E-type);
7. simple prefixes;
8. prefixes with arguments (argument processors);

```

1509 \cs_set_protected:Npn \__cmd_tmp:w #1 #2
1510 {
1511   \quark_if_nil:nF {#1}
1512   { \tl_const:cn { c__cmd_show_type_#1_tl } {#2} \__cmd_tmp:w }
1513 }
1514 \__cmd_tmp:w t0 r1 d1 R2 D2 O3 e4 E5 +6 !6 >7 =7 \q_nil \q_nil

```

Now, based on each type we know how to act. In most cases it is just a matter of feeding in the grabbed arguments and resuming the loop. The embellishments require a bit more attention: the e-type loops through the list of embellishments and adds each to the token list as a separate argument. The E-type does more or less the same, but uses `\__cmd_tl_mapthread_function:nnN` to map over two lists simultaneously, adding each token and default to the token list for printing.

```

1515 \cs_new_protected:Npn \__cmd_show_delim:Nw #1 #2
1516 { \__cmd_split_end_item:n { #1 #2 } \__cmd_split_signature_loop:Nw }
1517 \cs_new_protected:Npn \__cmd_show_delims:Nw #1 #2 #3
1518 { \__cmd_split_end_item:n { #1 #2 #3 } \__cmd_split_signature_loop:Nw }
1519 \cs_new_protected:Npn \__cmd_show_delims_opt:Nw #1 #2 #3 #4
1520 { \__cmd_split_end_item:n { #1 #2 #3 {#4} } \__cmd_split_signature_loop:Nw }
1521 \cs_new_protected:Npn \__cmd_show_opt:Nw #1 #2
1522 { \__cmd_split_end_item:n { #1 {#2} } \__cmd_split_signature_loop:Nw }
1523 \cs_new_protected:Npn \__cmd_show_e:Nw #1 #2
1524 {
1525   \tl_map_inline:nn {#2}
1526   {
1527     \__cmd_split_start_item:
1528     \__cmd_split_end_item:n { #1 {#1} }
1529   }
1530   \__cmd_split_signature_loop:Nw
1531 }
1532 \cs_set_protected:Npn \__cmd_tmp:w #1
1533 {
1534   \cs_new_protected:Npn \__cmd_show_E:Nw ##1 ##2 ##3
1535   {
1536     \cs_set_protected:Npn \__cmd_tmp:w #####1 #####2
1537     {
1538       \__cmd_split_start_item:
1539       \__cmd_split_end_item:n { ##1 #####1 {#####2} }
1540     }
1541     \__cmd_tl_mapthread_function:nnN {##2}
1542     { ##3 {#1} {#1} {#1} {#1} {#1} {#1} {#1} {#1} {#1} {#1} } \__cmd_tmp:w
1543     \__cmd_split_signature_loop:Nw
1544   }
1545 }
1546 \exp_args:NW \__cmd_tmp:w \c_novalue_tl

```

Minor wrinkle with the prefixes: they use `\__cmd_split_add_item:n` instead of `\__cmd_split_end_item:n` (add *vs.* end) because they are followed by an argument, so they can't end the item.

```

1547 \cs_new_protected:Npn \__cmd_show_prefix:Nw #1
1548 { \__cmd_split_add_item:n {#1} \__cmd_split_signature_loop:Nw }
1549 \cs_new_protected:Npn \__cmd_show_processor:Nw #1 #2
1550 { \__cmd_split_add_item:n { #1 {#2} } \__cmd_split_signature_loop:Nw }

```

And now the auxiliaries that store the strings to be printed. `\__cmd_split_start_item:` starts an item from scratch, `\__cmd_split_add_item:n` adds tokens to an item without adding a newline, and `\__cmd_split_end_item:n` adds tokens, terminates the item with a newline, and steps the argument count.

```

1551 \cs_new_protected:Npn \__cmd_split_start_item:
1552 {
1553   \tl_set:Nx \l__cmd_tmpb_tl
1554   { ~ \c_space_tl \c_hash_str \int_use:N \l__cmd_current_arg_int : }
1555 }
1556 \cs_new_protected:Npn \__cmd_split_add_item:n #1
1557 { \tl_put_right:Nx \l__cmd_tmpb_tl { \tl_to_str:n {#1} } }
1558 \cs_new_protected:Npn \__cmd_split_end_item:n #1
1559 {
1560   \tl_put_right:Nx \l__cmd_tmpa_tl
1561   { \l__cmd_tmpb_tl \tl_to_str:n {#1} \iow_newline: }
1562   \tl_clear:N \l__cmd_tmpb_tl
1563   \int_incr:N \l__cmd_current_arg_int
1564 }

```

(End of definition for `\__cmd_split_signature:n` and others.)

Not much to do regarding `latexrelease`: we could remove the entries from `\@showcommandlisthook`, but it doesn't seem worth it.

```

\__cmd_split_start_item: 1565 <latexrelease>\EndIncludeInRelease
\__cmd_split_add_item:n 1566 %
\__cmd_split_end_item:n 1567 <latexrelease>\IncludeInRelease{2020/10/01}{\__cmd_show:N (part 2)}%
1568 <latexrelease> {Support~\ShowCommand~in~ltcmd}
1569 <latexrelease>\EndIncludeInRelease

```

## 1.8 Grabbing arguments

All of the grabbers follow the same basic pattern. The initial function stores in `\l__cmd_signature_tl` the code to grab further arguments, defines (the function in) `\l__cmd_fn_tl` that will grab the argument, and calls it.

Defining `\l__cmd_fn_tl` means determining whether to use `\cs_set:Npn` or `\cs_set_nopar:Npn`, and for optional arguments whether to skip spaces. Once the argument is found, `\l__cmd_fn_tl` calls `\__cmd_add_arg:n`, responsible for calling processors and grabbing further arguments.

<pre> \__cmd_grab_b:w \__cmd_grab_b_long:w \__cmd_grab_b_obey_spaces:w \__cmd_grab_b_long_obey_spaces:w \__cmd_grab_b_aux:NNw \__cmd_grab_b_end:Nw </pre>	<p>This uses the well-tested code of D-type arguments, skipping the peeking step because the b-type argument is always present, and adding a cleanup stage at the end by hijacking the signature. The clean-up consists of properly dealing with <code>\l__cmd_args_tl</code> and also putting back the <code>\end</code> that served as an end-delimiter: this <code>\end</code> receives the environment name as its argument and is run normally. The D-type code stores the argument found (body of the environment) as a brace group in <code>\l__cmd_args_tl</code> and depending on the presence of a prefix <code>!</code> we trim spaces or not before adding this braced argument into the saved <code>\l__cmd_args_tl</code>. The strange <code>\begin_</code> control sequence is there for display purposes only: it has to look like <code>\begin</code> in the terminal but not to delimited arguments.</p>

```

(End of definition for `\__cmd_grab_c:w` and others.)

`\__cmd_grab_c_auxi:w` We need to see if the current line contains `\end` followed by the name of the current environment. To do that and allow for spaces, we have to work stepwise. First, establish `\__cmd_grab_c_auxii:w` if there is an `\end` at all: remember that here we are dealing with “other” tokens. Whether `\__cmd_grab_c_auxiii:N` these is an `\end` or not, the tokens *before* it form part of the line.

```

1641 \use:e
1642 {

1652   }
1653   { \__cmd_grab_c_auxii:w #2 \scan_stop: }
1654 }

```

There is an `\end`, so we now remove the trailing marker we needed to do the test. This is stripped off, then we need to examine the rest of the line one token at a time: see `verbatim.dtx` for the inspiration. Notice that we use `\^^M` here as the end marker: this allows looping to look for multiple `\end` entries in the line.

```

1655 \group_begin:
1656   \char_set_catcode_other:N \^^M %
1657   \use:e %

1666 } %

```

Within the line, we need to collect up the tokens: if we do not find the end-of-environment argument, we will need those to reinsert. There are three special cases here: ^^M (end of line: tidy up and back to the main loop), \ (possibly skip over) and { (start the inner loop). Anything else means we move back to examine the rest of the line for any more \end entries.

```

```

In the inner loop, we again have only a few special cases. First, we could again have ^^M, in which case we tidy up using a common auxiliary. Second, we check for the escape char: this cannot happen inside the end of an environment and means we loop, re-inserting the token. Finally, we have }, where we need to move on to check what has been collected. Otherwise, collect up and loop. Notice here that the inner loop needs to

collect tokens separately: this leaves any spaces after \end in \l\_\_cmd\_tmpa\_tl, so we can test \l\_\_cmd\_tmpb\_tl directly.

```

This is a bit complicated. The idea is that, in order to check for nested optional argument tokens (`[ [...]]` and so on) the argument needs to be grabbed without removing any braces at all. If this is not done, then cases like `[{[]]` fail. So after testing for an optional argument, it is collected piece-wise. Inserting a quark prevents loss of braces, and there is then a test to see if there are nested delimiters to handle.

```

Inside the “standard” grabber, there is a test to see if the grabbed argument is entirely enclosed by braces. There are a couple of extra factors to allow for: the argument might be entirely empty, and spaces at the start and end of the input must be retained around a brace group. Also notice that a *blank* argument might still contain spaces. To allow for suppression of brace stripping, the business end is passed here as #5.

```

Catching nested optional arguments means more work. The aim here is to collect up each pair of optional tokens without T<sub>E</sub>X helping out, and without counting anything. The code above will already have removed the leading opening token and a closing token, but the wrong one. The aim is then to work through the material grabbed so far and divide it up on each opening token, grabbing a closing token to match (thus working in pairs). Once there are no opening tokens, then there is a second check to see if there are any opening tokens in the second part of the argument (for things like `[] []`). Once everything has been found, the entire collected material is added to the output as a single argument. The only tricky part here is ensuring that any grabbing function that might run away is named after the function currently being parsed and not after `xparse`. That leads to some rather complex nesting! There is also a need to prevent the loss of any braces, hence the insertion and removal of quarks along the way.

`\__cmd_grab_D_call:Nw` For D and R-type arguments, to avoid losing any braces, a token needs to be inserted before the argument to be grabbed. If the argument runs away because the closing token is missing then this inserted token shows up in the terminal. Ideally, `#1` would therefore be used directly, but that is no good as it will mess up the rest of the grabber. Instead, a copy of `#1` with an altered category code is used, as this will look right in the terminal but will not mess up the grabber. The only issue then is that the category code of `#1` is unknown. So there is a quick test to ensure that the inserted token can never be matched by the grabber. (This assumes that the open and close delimiters are not the same character with different category codes, but that really should not happen in any sensible document-level syntax.) An exception is when `#1` is a control sequence token, in which case the character-token treatment is no good because if hit with `\token_to_str:N` it would add sputios tokens to the argument. In this case a different branch is taken. The token inserted is then the same `<csname>` as `#1`, but with a space appended, so that the grabber don't see it as another of the same delimiter.

`\l__cmd_v_arg_tl` 2084 `\tl_new:N \l__cmd_v_arg_tl`

`\__cmd_grab_v:w` Firstly, it is necessary to change `\tex_endlinechar:D` so that newlines in different cat-  
`\__cmd_grab_v_long:w` code regimes (e.g., `\ExplSyntaxOn`) are not misinterpreted as spaces. The opening de-  
`\__cmd_grab_v_aux:w` limiter is the first non-space token, and is never read verbatim. This is required by  
`\__cmd_grab_v_group_end:` consistency with the case where the preceding argument was optional and absent: then  
 $\TeX$  has already read and tokenized that token when looking for the optional argument.  
 The first thing is thus to check is that this delimiter is a character, and to distinguish

the case of a left brace (in that case, `\group_align_safe_end:` is needed to compensate for the begin-group character that was just seen). Then set verbatim catcodes with `\__cmd_grab_v_aux_catcodes:`.

The group keep catcode changes local, and `\group_align_safe_begin/end:` allow to use a character with category code 4 (normally `&`) as the delimiter (all commands do `\group_align_safe_begin/end:`, so there's no need to do that again here). It is ended by `\__cmd_grab_v_group_end:`, which smuggles the collected argument out of the group.

<code>\__cmd_grab_v_aux_test:N</code> <code>\__cmd_grab_v_aux_loop:N</code> <code>\__cmd_grab_v_aux_loop:NN</code> <code>\__cmd_grab_v_aux_loop_end:</code>	Check that the opening delimiter is a character, setup category codes, then start reading tokens one by one, keeping the delimiter as an argument. If the verbatim was not nested, we will be grabbing one character at each step. Unfortunately, it can happen that what follows the verbatim argument is already tokenized. Thus, we check at each step that the next token is indeed a “nice” character, <i>i.e.</i> , is not a character with category code
--	---

1 (begin-group), 2 (end-group) or 6 (macro parameter), nor the space character, with category code 10 and character code 32, nor a control sequence. The partially built argument is stored in `\l__cmd_v_arg_tl`. If we ever meet a token which we cannot grab (non-N-type), or which is not a character according to `\__cmd_grab_v_token_if_char:N`, then we bail out with `\__cmd_grab_v_aux_abort:n`. Otherwise, we stop at the first character matching the delimiter.

## `\l__cmd_v_nesting_int`

```

2156 \int_new:N \l__cmd_v_nesting_int

```

`\__cmd_grab_v_bgroup:` If the opening delimiter is a left brace, we keep track of how many left and right braces were encountered so far in `\l__cmd_v_nesting_int` (the methods used for optional arguments cannot apply here), and stop as soon as it reaches 0.

Some care was needed when removing the opening delimiter, which has already been assigned category code 1: using `\peek_meaning_remove:N` in the `\__cmd_grab_v_aux:w` function would break within alignments. Instead, we first convert that token to a string, and remove the result as a normal undelimited argument.

```

(End of definition for \\_\_cmd\_add\_arg:n.)

## 1.9 Grabbing arguments expandably

\\_\_cmd\_expandable\_grab\_D:w  
\\_\_cmd\_expandable\_grab\_D:NNNwNNn  
\\_\_cmd\_expandable\_grab\_D:NNNwNNnn  
\\_\_cmd\_expandable\_grab\_D:Nw  
\\_\_cmd\_expandable\_grab\_D:nnNNwNN

The first step is to grab the first token or group. The generic grabbers \<function>\_ and \<function>\_ are just after \q\_\_cmd, we go and find them (and use the long one).

```

2284 \cs_new:Npn \__cmd_expandable_grab_D:w #1 \q__cmd #2#3
2285 { #2 { \__cmd_expandable_grab_D:NNNwNNn #1 \q__cmd #2 #3 } }

```

We then wish to test whether #7, which we just grabbed, is exactly #2. A preliminary test is whether their string representations coincide, then expand the only grabber function we have, #1, once: the two strings below are equal if and only if #7 matches #2 exactly.<sup>2</sup> The preliminary test is needed as #7 could validly contain \par (because a later mandatory argument could be long) and our grabber may be short. If #7 does not match #2, then the optional argument is missing, we use the default -NoValue-, and put back the argument #7 in the input stream.

If it does match, then interesting things need to be done. We will grab the argument piece by piece, with the following pattern:

```

<grabber> {<tokens>}
\q_nil {<piece 1>} <piece 2> \ERROR \q__cmd
\q_nil <input stream>

```

The <grabber> will find an opening delimiter in <piece 2>, take the \q\_\_cmd as a second delimiter, and find more material delimited by the closing delimiter in the <input stream>. We then move the part before the opening delimiter from <piece 2> to <piece 1>, and the material taken from the <input stream> to the <piece 2>. Thus, the argument moves gradually from the <input stream> to the <piece 2>, then to the <piece 1> when we have made sure to find all opening and closing delimiters. This two-step process ensures that nesting works: the number of opening delimiters minus closing delimiters in <piece 1> is always equal to the number of closing delimiters in <piece 2>. We stop grabbing arguments once the <piece 2> contains no opening delimiter any more, hence the balance is reached, and the final argument is <piece 1> <piece 2>. The indirection via \\_\_cmd\_tmp:w allows to insert -NoValue- expanded.

```

2286 \cs_set_protected:Npn \__cmd_tmp:w #1
2287 {
2288   \cs_new:Npn \__cmd_expandable_grab_D:NNNwNNn ##1##2##3##4 \q__cmd ##5##6##7
2289   {
2290     \str_if_eq:nnTF {##2} {##7}
2291     {
2292       \str_if_eq:onTF
2293       { ##1 { } { } ##7 ##2 \q__cmd ##3 }
2294       { { } {##2} { } }
2295     }
2296     { \use_ii:nn }
2297     {
2298       ##1
2299       { \__cmd_expandable_grab_D:NNNwNNnn ##1##2##3##4 \q__cmd ##5##6 }
2300       \q_nil { } ##2 \ERROR \q__cmd \ERROR
2301     }
2302     { ##4 {##1} \q__cmd ##5 ##6 {##7} }
2303   }
2304 }
2305 \exp_args:No \__cmd_tmp:w { \c_novalue_tl }

```

<sup>2</sup>It is obvious that if #7 matches #2 then the strings are equal. We must check the converse. The right-hand-side of \str\_if\_eq:onTF does not end with #3, implying that the grabber function took everything as its arguments. The first brace group can only be empty if #7 starts with #2, otherwise the brace group preceding #7 would not vanish. The third brace group is empty, thus the \q\_\_cmd that was used by our grabber #1 must be the one that we inserted (not some token in #7), hence the second brace group contains the end of #7 followed by #2. Since this is #2 on the right-hand-side, and no brace can be lost there, #7 must contain nothing else than its leading #2.

At this stage, #7 is `\q_nil {<piece 1>} <more for piece 1>`, and we want to concatenate all that, removing `\q_nil`, and keeping the opening delimiter #2. Simply use `\use_ii:nn`. Also, #8 is `<remainder of piece 2> \ERROR`, and #9 is `\ERROR <more for piece 2>`. We concatenate those, replacing the two `\ERROR` by the closing delimiter #3.

```

2306 \cs_new:Npn \__cmd_expandable_grab_D:NNNwNNnnn #1#2#3#4 \q__cmd #5#6#7#8#9
2307 {
2308   \exp_args:Nof \__cmd_expandable_grab_D:nnNNwNN
2309   { \use_ii:nn #7 #2 }
2310   { \__cmd_expandable_grab_D:Nw #3 \exp_stop_f: #8 #9 }
2311   #1#2#3 #4 \q__cmd #5 #6
2312 }
2313 \cs_new:Npn \__cmd_expandable_grab_D:Nw #1#2 \ERROR \ERROR { #2 #1 }

```

Armed with our two new `<pieces>`, we are ready to loop. However, we must first see if `<piece 2>` (here #2) contains any opening delimiter #4. Again, we expand #3, this time removing its whole output with `\use_none:nnn`. The test is similar to `\tl_if_in:nnTF`. The token list is empty if and only if #2 does not contain the opening delimiter. In that case, we are done, and put the argument (from which we remove a spurious pair of delimiters coming from how we started the loop). Otherwise, we go back to looping with `\__cmd_expandable_grab_D:NNNwNNnnn`. The code to deal with brace stripping is much the same as for the non-expandable case.

```

 \\_\_cmd\_expandable\_grab\_E\_find:nnw  
 \\_\_cmd\_expandable\_grab\_E\_end:nnw

We keep track of long/short by placing the appropriate grabber as the third token after \q\_\_cmd; it is eventually removed by the `end:nnw` auxiliary. The `aux:w` auxiliary will be called repeatedly with two arguments: the set of pairs  $\langle \textit{parser} \rangle \langle \textit{token} \rangle$ , and the set of arguments found so far (initially all  $\{-\textit{NoValue}-\}$ ). At each step, grab what follows in the input stream then call the `loop:nnnNNw` auxiliary to compare it with each possible embellishment in turn. This auxiliary's #1 is what was found in the input, #2 collects  $\langle \textit{parser} \rangle \langle \textit{token} \rangle$  pairs that did not match, #3 collects the corresponding arguments found previously, #4 and #5 is the current pair, #6 is the remaining pairs, #7 is empty or two \q\_nil, and #8 is the current argument. If none of the pairs matched (determined by `\quark_if_nil:NTF`) then call the `end` auxiliary to stop looking for embellishments, remembering to put what was grabbed in the input back where it belongs, and storing the arguments found just before \q\_\_cmd. If the current argument #8 is not `-NoValue-` or if the input #1 does not match #5 (see `t-type` arguments below for a similar `\str_if_eq:onTF` test) then carry on the loop. Otherwise, we found a new embellishment: grab the corresponding argument in the input using the `find:w` auxiliary. To avoid losing braces around that auxiliary's argument we include a space, which will be eliminated in the next loop through embellishments.

```

2371 \cs_new:Npn \__cmd_expandable_grab_E:w #1 \q__cmd #2#3

```

```

## 1.11 Conversion to key–value form

This is implemented as a process but with no public interfaces, hence is treated separately from the others: it's a feature of ltcmd which just happens to use the same mechanism as a processor.

`\__cmd_arg_to_keyvalue:nn`  
`\_cmd_arg_to_keyvalue_braces:nnn`  
`\_cmd_arg_to_keyvalue_auxi:nnn`  
`\_cmd_arg_to_keyvalue_auxii:Nnnn`  
`\_cmd_arg_to_keyvalue_auxiii:nnn`  
`\_cmd_arg_to_keyvalue_auxiv:Nnnn`  
`\_cmd_arg_to_keyvalue_auxv:nn`  
`\_cmd_arg_to_keyvalue_loop:w`  
`\_cmd_arg_to_keyvalue_loop_group:n`  
`\_cmd_arg_to_keyvalue_loop_space:w`  
`\_cmd_arg_to_keyvalue_loop_N_type:N`  
`\_cmd_arg_to_keyvalue_math:w`  
`\_cmd_arg_to_keyvalue_math_N_type:N`  
`\_cmd_arg_to_keyvalue_math_group:n`  
`\_cmd_arg_to_keyvalue_math_space:w`  
`\_cmd_arg_to_keyvalue_set_default:nn`  
`\_cmd_arg_to_keyvalue_set_keyvalue:nn`  
`\__cmd_split_N_head_apply:Nn`  
`\_cmd_split_N_head_apply_aux:NNw`

If the entire argument is braced, we treat as free text and return as the value for the text key. Alternatively, if the start of the input is =, then it is forced to be key-value. To avoid needing to worry about catcodes for this, and to allow spaces around the =, we use a series of steps rather than a delimited argument.

```

2602 }

```

The two clear-cut cases have been eliminated, and we therefore have to deal with a search for = signs. We need an “action” loop here so we do not get misled by for example {=}. As the code here is for very much predictable types of input, we hard-code what constitutes math mode opening and closing. At the very beginning, the default key (#1) and the argument as given by the user (#2) are placed right after the `\q__cmd_recursion_stop`, so that when the recursion ends, the macros `\__cmd_arg_to_keyvalue_set_default:nn` or `\__cmd_arg_to_keyvalue_set_keyvalue:nn` can be used to grab these two items and

set the \ProcessedArgument accordingly.

## 1.12 Utilities

```

\__cmd_check_definable:nNT
  \__cmd_check_definable_aux:nN

```

Check that a token list is appropriate as a first argument of `\NewDocumentCommand` and similar functions and otherwise produce an error. First trim whitespace to allow for spaces around the actual command to be defined. If the result has multiple tokens, it is not a valid argument. The single token is a control sequence exactly if its string representation has more than one character (using `\token_to_str:N` rather than `\tl_to_str:n` to avoid problems with macro parameter characters, and setting `\tex_escapechar:D` to prevent it from being non-printable). Finally, check for an active character: this is done by lowercasing the token to fix its character code (arbitrarily to that of `?`) and comparing the result to an active `?`. Both control sequences and active characters are valid arguments, and non-active character tokens are not. In all cases, the group opened to keep assignments local must be closed.

```

2677 \cs_new_protected:Npn \__cmd_check_definable:nNT #1
2678 { \tl_trim_spaces_apply:nN {#1} \__cmd_check_definable_aux:nN }
2679 \group_begin:

2707 }
2708 \group_end:

```

(End of definition for `\__cmd_check_definable:nNT` and `\__cmd_check_definable_aux:nN`.)

`\__cmd_token_if_cs:NTF` Based on the definition of `\__cmd_check_definable_aux:nN` above, but only checks for an actual control sequence (*i.e.*, `\<anything>`). `\tex_escapechar:D` is temporarily changed to a known value and then it checks if `\string#1` contains more than one character: if it does, it's a control sequence. This test differs from `\token_if_cs:NTF` for example in `\token_if_cs:NTF \c_group_begin_token {T}{F}`, where `\token_if_cs:NTF` returns false.

```

2709 \cs_new_protected:Npn \__cmd_token_if_cs:NTF #1
2710 {
2711     \group_begin:
2712     \int_set:Nn \tex_escapechar:D { 92 }

### 1.13 Access to the argument specification

`\cmd_arg_spec:N` First we check that the command passed does exist, and is one with the correct form.  
`\cmd_arg_spec:c` If it does then there are two cases. For optimised commands, we can reconstruct the  
`\__cmd_arg_spec_opt:N` arg. spec. from the T<sub>E</sub>X parameter spec, taking care to add + if required. For the non-  
optimized cases, the arg. spec. is stored in the top-level macro. We treat this as a `tl` and  
extract the appropriate balanced text: the second item.

```

2817 \cs_new:Npn \cmd_arg_spec:N #1
2818 {
2819   \cs_if_exist:NTF #1
2820   {

## 1.15 User functions

The user functions are more or less just the internal functions renamed.

`\BooleanFalse` Design-space names for the Boolean values.

```

\BooleanTrue 3115 \cs_new_eq:NN \BooleanFalse \c_false_bool
3116 \cs_new_eq:NN \BooleanTrue \c_true_bool

```

*(End of definition for \BooleanFalse and \BooleanTrue.)*

`\NewDocumentCommand` The user macros are pretty simple wrappers around the internal ones. There is however  
`\RenewDocumentCommand` a check that the first argument is a single token, possibly surrounded by spaces (hence  
`\ProvideDocumentCommand` the strange `\use:nnn`), and is definable.  
`\DeclareDocumentCommand`

```

3117 \cs_new_protected:Npn \NewDocumentCommand #1#2#3
3118 {
3119   \__cmd_check_definable:nNT {#1} \NewDocumentCommand
3120   {
3121     \cs_if_exist:NTF #1
3122     {
3123       \msg_error:nnxx { cmd } { already-defined }
3124       { \use:nnn \token_to_str:N #1 { } }
3125       { \token_to_str:N \NewDocumentCommand }
3126     }
3127     { \__cmd_declare_cmd:Nnn #1 {#2} {#3} }
3128   }
3129 }
3130 \cs_new_protected:Npn \RenewDocumentCommand #1#2#3
3131 {
3132   \__cmd_check_definable:nNT {#1} \RenewDocumentCommand
3133   {
3134     \cs_if_exist:NTF #1
3135     { \__cmd_declare_cmd:Nnn #1 {#2} {#3} }
3136     {
3137       \msg_error:nnxx { cmd } { undefined }
3138       { \use:nnn \token_to_str:N #1 { } }
3139       { \token_to_str:N \RenewDocumentCommand }
3140     }
3141   }
3142 }
3143 \cs_new_protected:Npn \ProvideDocumentCommand #1#2#3
3144 {
3145   \__cmd_check_definable:nNT {#1} \ProvideDocumentCommand
3146   { \cs_if_exist:NF #1 { \__cmd_declare_cmd:Nnn #1 {#2} {#3} } }
3147 }
3148 \cs_new_protected:Npn \DeclareDocumentCommand #1#2#3
3149 {
3150   \__cmd_check_definable:nNT {#1} \DeclareDocumentCommand

```

```

3151     { \_cmd_declare_cmd:Nnn #1 {#2} {#3} }
3152   }

```

(End of definition for \NewDocumentCommand and others.)

\NewDocumentEnvironment Very similar for environments. Trim spaces from user-specified `<envname>`, do existence check then hand off to `\_cmd_declare_env:nnnn`.

```

\RenewDocumentEnvironment
\ProvideDocumentEnvironment 3153 <latexrelease>\IncludeInRelease{2024/11/01}{\NewDocumentEnvironment}%

3274   }

```

*(End of definition for \NewExpandableDocumentCommand and others.)*

**\IfBooleanT** The logical `<true>` and `<false>` statements are just the normal `\c_true_bool` and `\c_false_bool` so `\bool_if:NTF` is almost enough. However, this code-level function blows up badly when passed invalid input. We want `\IfBooleanTF` to accept a single (non-space) token equal to `\c_true_bool` or `\c_false_bool`, possibly surrounded by spaces. If the input is blank or multiple items, jump to the error and pick the false branch. If the input, ignoring spaces (we do this by omitting braces in the `\tl_if_single_token:nF` test), is not a single token then jump to the error as well. It is then safe to compare the token to the two booleans, picking the appropriate branch. If neither matches, we jump to the error as well.

```

3275   \cs_new:Npn \IfBooleanTF #1
3276   {
3277     \tl_if_single:nF {#1}
3278     { \prg_break:n { \use:n } }

```

```

3289     \use_ii:nn
3290   }
3291 }
3292 \cs_new:Npn \IfBooleanT #1#2 { \IfBooleanTF {#1} {#2} { } }
3293 \cs_new:Npn \IfBooleanF #1 { \IfBooleanTF {#1} { } }

```

(End of definition for \IfBooleanT, \IfBooleanF, and \IfBooleanTF.)

\IfNoValueT Simple re-naming.

```

\IfNoValueF 3294 \cs_new_eq:NN \IfNoValueF \tl_if_novalue:nF
\IfNoValueTF 3295 \cs_new_eq:NN \IfNoValueT \tl_if_novalue:nT
3296 \cs_new_eq:NN \IfNoValueTF \tl_if_novalue:nTF

```

(End of definition for \IfNoValueT, \IfNoValueF, and \IfNoValueTF.)

\IfValueT Inverted logic.

```

\IfValueF 3297 \cs_new:Npn \IfValueF { \tl_if_novalue:nT }
\IfValueTF 3298 \cs_new:Npn \IfValueT { \tl_if_novalue:nF }
3299 \cs_new:Npn \IfValueTF #1#2#3 { \tl_if_novalue:nTF {#1} {#3} {#2} }

```

(End of definition for \IfValueT, \IfValueF, and \IfValueTF.)

\IfBlankT Another simple re-naming.

```

\IfBlankF 3300 <latexrelease> \IncludeInRelease{2022/06/01}%
\IfBlankTF 3301 <latexrelease> { \IfBlankTF } { Testing-for-empty-or-blank } %
3302 \cs_new_eq:NN \IfBlankF \tl_if_blank:nF
3303 \cs_new_eq:NN \IfBlankT \tl_if_blank:nT
3304 \cs_new_eq:NN \IfBlankTF \tl_if_blank:nTF
3305 <latexrelease> \EndIncludeInRelease
3306 <latexrelease> \IncludeInRelease{2021/11/15}%
3307 <latexrelease> { \IfBlankTF } { Testing-for-empty-or-blank } %
3308 <latexrelease> \cs_undefine:N \IfBlankF
3309 <latexrelease> \cs_undefine:N \IfBlankT
3310 <latexrelease> \cs_undefine:N \IfBlankTF
3311 <latexrelease>
3312 <latexrelease> \EndIncludeInRelease

```

(End of definition for \IfBlankT, \IfBlankF, and \IfBlankTF.)

\ProcessedArgument Processed arguments are returned using this name, which is reserved here although the definition will change.

```

3313 \tl_new:N \ProcessedArgument

```

(End of definition for \ProcessedArgument.)

\ReverseBoolean Simple copies.

```

\SplitArgument 3314 \cs_new_eq:NN \ReverseBoolean \__cmd_bool_reverse:N
\SplitList 3315 \cs_new_eq:NN \SplitArgument \__cmd_split_argument:nnn
\TrimSpaces 3316 \cs_new_eq:NN \SplitList \__cmd_split_list:nn
3317 \cs_new_eq:NN \TrimSpaces \__cmd_trim_spaces:n

```

(End of definition for \ReverseBoolean and others.)

\ProcessList To support \SplitList.

```

3318 \cs_new_eq:NN \ProcessList \tl_map_tokens:nn

```

(End of definition for \ProcessList.)

Finally as promised, restore \\_kernel\_chk\_if\_free\_cs:N:

```
3319 <latexrelease>\cs_gset_eq:NN \_kernel_chk_if_free_cs:N \_cmd_chk_if_free_cs:N
```

```
3320 <latexrelease>\cs_undefine:N \_cmd_chk_if_free_cs:N
```

```
3321 <latexrelease>
```

```
3322 <latexrelease>\IncludeInRelease{0000/00/00}{ltxcmd}%
```

```
3323 <latexrelease>{Document~command~parser}%
```

```
3324 <latexrelease>
```

```
3325 <latexrelease>\EndModuleRelease
```

```
3326 \ExplSyntaxOff
```

Now in latexrelease mode, redefine \NewDocumentCommand to not complain on commands already defined.

```
3327 <latexrelease>\@ifundefined{ExplSyntaxOff}{\{\}\latexrelease@postltxcmd}
```

```
3328 <latexrelease>\catcode'\^@=\@latexrelease@catcode@null\relax
```

```
3329 </2ekernel | latexrelease>
```

We need to stop DocStrip treating @@ in a special way at this point.

```
3330 <@@=>
```

## File 08

# lthooks.dtx

## 1 Introduction

Hooks are points in the code of commands or environments where it is possible to add processing code into existing commands. This can be done by different packages that do not know about each other, and to allow for hopefully safe processing it is necessary to sort different chunks of code added by different packages into a suitable processing order.

This is done by the packages adding chunks of code (via `\AddToHook`) and labeling their code with some label by default using the package name as a label.

At `\begin{document}` all code for a hook is then sorted according to some rules (given by `\DeclareHookRule`) for fast execution without processing overhead. If the hook code is modified afterwards (or the rules are changed), a new version for fast processing is generated.

Some hooks are used already in the preamble of the document. If that happens then the hook is prepared for execution (and sorted) already at that point.

## 2 Package writer interface

The hook management system is offered as a set of CamelCase commands for traditional  $\text{\LaTeX 2}_\epsilon$  packages (and for use in the document preamble if needed) as well as `expl3` commands for modern packages, that use the L3 programming layer of  $\text{\LaTeX}$ . Behind the scenes, a single set of data structures is accessed so that packages from both worlds can coexist and access hooks in other packages.

### 2.1 $\text{\LaTeX 2}_\epsilon$ interfaces

#### 2.1.1 Declaring hooks

With a few exceptions, hooks have to be declared before they can be used. The exceptions are the generic hooks for commands and environments (executed at `\begin` and `\end`), and the generic hooks run when loading files (see section 3.1).

---

<code>\NewHook</code>	<code>\NewHook {&lt;hook&gt;}</code>
-----------------------	--------------------------------------

Creates a new `<hook>`. If this hook is declared within a package it is suggested that its name is always structured as follows: `<package-name>/<hook-name>`. If necessary you can further subdivide the name by adding more / parts. If a hook name is already taken, an error is raised and the hook is not created.

The `<hook>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5. The string `??` can't be used as a hook name because it has a special significance as a placeholder in hook rules.

---

<code>\NewReversedHook</code>	<code>\NewReversedHook {⟨hook⟩}</code>
-------------------------------	--

---

Like `\NewHook` declares a new `⟨hook⟩`. the difference is that the code chunks for this hook are in reverse order by default (those added last are executed first). Any rules for the hook are applied after the default ordering. See sections 2.3 and 2.4 for further details.

The `⟨hook⟩` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\NewMirroredHookPair</code>	<code>\NewMirroredHookPair {⟨hook-1⟩} {⟨hook-2⟩}</code>
-----------------------------------	---

---

A shorthand for `\NewHook{⟨hook-1⟩}\NewReversedHook{⟨hook-2⟩}`.

The `⟨hook⟩` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\NewHookWithArguments</code>	<code>\NewHookWithArguments {⟨hook⟩} {⟨number⟩}</code>
------------------------------------	--

---

Creates a new `⟨hook⟩` whose code takes `⟨number⟩` arguments, and otherwise works exactly like `\NewHook`. Section 2.7 explains hooks with arguments.

The `⟨hook⟩` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\NewReversedHookWithArguments</code>	<code>\NewReversedHookWithArguments {⟨hook⟩} {⟨number⟩}</code>
--	--

---

Like `\NewReversedHook`, but creates a hook whose code takes `⟨number⟩` arguments. Section 2.7 explains hooks with arguments.

The `⟨hook⟩` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\NewMirroredHookPairWithArguments</code>	<code>\NewMirroredHookPairWithArguments {⟨hook-1⟩} {⟨hook-2⟩} {⟨number⟩}</code>
--	---

---

A shorthand for `\NewHookWithArguments{⟨hook-1⟩}{⟨number⟩}`

`\NewReversedHookWithArguments{⟨hook-2⟩}{⟨number⟩}`. Section 2.7 explains hooks with arguments.

The `⟨hook⟩` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

## 2.1.2 Special declarations for generic hooks

The declarations here should normally not be used. They are available to provide support for special use cases mainly involving generic command hooks.

---

<code>\DisableGenericHook</code>	<code>\DisableGenericHook {⟨hook⟩}</code>
----------------------------------	---

---

After this declaration<sup>3</sup> the `⟨hook⟩` is no longer usable: Any further attempt to add code to it will result in an error and any use, e.g., via `\UseHook`, will simply do nothing.

This is intended to be used with generic command hooks (see `lthcmdhooks-doc`) as depending on the definition of the command such generic hooks may be unusable. If that is known, a package developer can disable such hooks up front.

The `⟨hook⟩` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<sup>3</sup>In the 2020/06 release this command was called `\DisableHook`, but that name was misleading as it shouldn't be used to disable non-generic hooks.

---

<hr/> <code>\ActivateGenericHook</code> <hr/>	<code>\ActivateGenericHook {⟨hook⟩}</code>
---	--

This declaration activates a generic hook provided by a package/class (e.g., one used in code with `\UseHook` or `\UseOneTimeHook`) without it being explicitly declared with `\NewHook`). If the hook is already activated, this command does nothing.

Note that this command does not undo the effect of `\DisableGenericHook`. See section 2.6 for a discussion of when this declaration is appropriate.

### 2.1.3 Using hooks in code

Using a hook that is executing the code that has been associated with it is only allowed if the hook has been previously declared with `\NewHook`. For performance reason there are no runtime checks for this and it is the responsibility of the programmer of a package to ensure that all hooks that are used in a package (with one of the commands in this section) are declared first.

---

<hr/> <code>\UseHook</code> <hr/>	<code>\UseHook {⟨hook⟩}</code>
-----------------------------------	--------------------------------

Execute the code stored in the `⟨hook⟩`.

Before `\begin{document}` the fast execution code for a hook is not set up, so in order to use a hook there it is explicitly initialized first. As that involves assignments using a hook at those times is not 100% the same as using it after `\begin{document}`.

The `⟨hook⟩` *cannot* be specified using the dot-syntax. A leading `.` is treated literally.

---

<hr/> <code>\UseHookWithArguments</code> <hr/>	<code>\UseHookWithArguments {⟨hook⟩} {⟨number⟩} {⟨arg<sub>1</sub>⟩} ... {⟨arg<sub>n</sub>⟩}</code>
--	--

Execute the code stored in the `⟨hook⟩` and pass the arguments `{⟨arg1⟩}` through `{⟨argn⟩}` to the `⟨hook⟩`. Otherwise, it works exactly like `\UseHook`. The `⟨number⟩` should be the number of arguments declared for the hook. If the hook is not declared, this command does nothing and it will remove `⟨number⟩` items from the input. Section 2.7 explains hooks with arguments.

The `⟨hook⟩` *cannot* be specified using the dot-syntax. A leading `.` is treated literally.

---

<hr/> <code>\UseOneTimeHook</code> <hr/>	<code>\UseOneTimeHook {⟨hook⟩}</code>
--	---------------------------------------

Some hooks are only used (and can be only used) in one place, for example, those in `\begin{document}` or `\end{document}`. From that point onwards, adding to the hook through a defined `\⟨addto-cmd⟩` command (e.g., `\AddToHook` or `\AtBeginDocument`, etc.) would have no effect (as would the use of such a command inside the hook code itself). It is therefore customary to redefine `\⟨addto-cmd⟩` to simply process its argument, i.e., essentially make it behave like `\@firstofone`.

`\UseOneTimeHook` does that: it records that the hook has been consumed and any further attempt to add to it will result in executing the code to be added immediately.

Using `\UseOneTimeHook` several times with the same `{⟨hook⟩}` means that it only executes the first time it is used. For example, if it is used in a command that can be called several times then the hook executes during only the *first* invocation of that command; this allows its use as an “initialization hook”.

Mixing `\UseHook` and `\UseOneTimeHook` for the same `{⟨hook⟩}` should be avoided, but if this is done then neither will execute after the first `\UseOneTimeHook`.

The `⟨hook⟩` *cannot* be specified using the dot-syntax. A leading `.` is treated literally. See section 2.1.5 for details.

---

<code>\UseOneTimeHookWithArguments</code>	<code>\UseOneTimeHookWithArguments {&lt;hook&gt;} {&lt;number&gt;} {&lt;arg<sub>1</sub>&gt;} ... {&lt;arg<sub>n</sub>&gt;}</code>
---	---

---

Works exactly like `\UseOneTimeHook`, but passes arguments  $\{<arg_1>\}$  through  $\{<arg_n>\}$  to the  $\langle\text{hook}\rangle$ . The  $\langle\text{number}\rangle$  should be the number of arguments declared for the hook. If the hook is not declared, this command does nothing and it will remove  $\langle\text{number}\rangle$  items from the input.

It should be noted that after a one-time hook is used, it is no longer possible to use `\AddToHookWithArguments` or similar with that hook. `\AddToHook` continues to work as normal. Section 2.7 explains hooks with arguments.

The  $\langle\text{hook}\rangle$  *cannot* be specified using the dot-syntax. A leading `.` is treated literally. See section 2.1.5 for details.

#### 2.1.4 Updating code for hooks

In contrast to the commands from the previous section, declarations such as `\AddToHook` or `\DeclareHookRule` can be used even when the hook is not yet declared. The rationale is that the hook declaration may be in some package that is loaded later, or perhaps not loaded at all.

A side effect of this design is that misspellings do not raise an error but are simply regarded as declarations for hooks with a different name.

---

<code>\AddToHook</code>	<code>\AddToHook {&lt;hook&gt;} [&lt;label&gt;] {&lt;code&gt;}</code>
-------------------------	---

---

Adds  $\langle\text{code}\rangle$  to the  $\langle\text{hook}\rangle$  labeled by  $\langle\text{label}\rangle$ . When the optional argument  $\langle\text{label}\rangle$  is not provided, the  $\langle\text{default label}\rangle$  is used (see section 2.1.5). If `\AddToHook` is used in a package/class, the  $\langle\text{default label}\rangle$  is the package/class name, otherwise it is `top-level` (the `top-level` label is treated differently: see section 2.1.6).

If there already exists code under the  $\langle\text{label}\rangle$  then the new  $\langle\text{code}\rangle$  is appended to the existing one (even if this is a reversed hook). If you want to replace existing code under the  $\langle\text{label}\rangle$ , first apply `\RemoveFromHook`.

The hook doesn't have to exist for code to be added to it. However, if it is not declared, then obviously the added  $\langle\text{code}\rangle$  will never be executed. This allows for hooks to work regardless of package loading order and enables packages to add to hooks from other packages without worrying whether they are actually used in the current document. See section 2.1.8.

The  $\langle\text{hook}\rangle$  and  $\langle\text{label}\rangle$  can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\AddToHookWithArguments</code>	<code>\AddToHookWithArguments {&lt;hook&gt;} [&lt;label&gt;] {&lt;code&gt;}</code>
--------------------------------------	--

---

Works exactly like `\AddToHook`, except that the `<code>` can access the arguments passed to the hook using `#1`, `#2`, ..., `#n` (up to the number of arguments declared for the hook). If the `<code>` should contain *parameter tokens* (`#`) that are not supposed to be understood as the arguments of the hook, such tokens should be doubled. For example, with `\AddToHook` one can write:

```
\AddToHook{myhook}{\def\foo#1{Hello, #1!}}
```

but to achieve the same with `\AddToHookWithArguments`, one should write:

```
\AddToHookWithArguments{myhook}{\def\foo##1{Hello, ##1!}}
```

because in the latter case, `#1` refers to the first argument of the hook `myhook`. Section 2.7 explains hooks with arguments.

The `<hook>` and `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\RemoveFromHook</code>	<code>\RemoveFromHook {&lt;hook&gt;} [&lt;label&gt;]</code>
------------------------------	---

---

Removes any code labeled by `<label>` from the `<hook>`. When the optional argument `<label>` is not provided, the `<default label>` is used (see section 2.1.5).

If there is no code under the `<label>` in the `<hook>`, or if the `<hook>` does not exist, a warning is issued when you attempt to `\RemoveFromHook`, and the command is ignored. `\RemoveFromHook` should be used only when you know exactly what labels are in a hook. Typically this will be when some code gets added to a hook by a package, then later this code is removed by that same package. If you want to prevent the execution of code from another package, use the `voids` rule instead (see section 2.1.7).

If the optional `<label>` argument is `*`, then all code chunks are removed. This is rather dangerous as it may well drop code from other packages (that one may not know about); it should therefore not be used in packages but only in document preambles!

The `<hook>` and `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

In contrast to the `voids` relationship between two labels in a `\DeclareHookRule` this is a destructive operation as the labeled code is removed from the hook data structure, whereas the relationship setting can be undone by providing a different relationship later.

A useful application for this declaration inside the document body is when one wants to temporarily add code to hooks and later remove it again, e.g.,

```
\AddToHook{env/quote/begin}{\small}
\begin{quote}
  A quote set in a smaller typeface
\end{quote}
...
\RemoveFromHook{env/quote/begin}
... now back to normal for further quotes
```

Note that you can't cancel the setting with

```
\AddToHook{env/quote/begin}{}
```

**Important:**

*The `\RemoveFromHook` command should be only used if one has full control over the code chunk to be removed. In particular it should not be used to remove code chunks from other packages! For this the `voids` relation is provided.*

because that only “adds” a further empty chunk of code to the hook. Adding `\normalsize` would work but that means the hook then contained `\small\normalsize` which means two font size changes for no good reason.

The above is only needed if one wants to typeset several quotes in a smaller typeface. If the hook is only needed once then `\AddToHookNext` is simpler, because it resets itself after one use.

---

**`\AddToHookNext`**    `\AddToHookNext {<hook>} {<code>}`

---

Adds `<code>` to the next invocation of the `<hook>`. The code is executed after the normal hook code has finished and it is executed only once, i.e. it is deleted after it was used.

Using this declaration is a global operation, i.e., the code is not lost even if the declaration is used inside a group and the next invocation of the hook happens after the end of that group. If the declaration is used several times before the hook is executed then all code is executed in the order in which it was declared.<sup>4</sup>

If this declaration is used with a one-time hook then the code is only ever used if the declaration comes before the hook’s invocation. This is because, in contrast to `\AddToHook`, the code in this declaration is not executed immediately in the case when the invocation of the hook has already happened—in other words, this code will truly execute only on the next invocation of the hook (and in the case of a one-time hook there is no such “next invocation”). This gives you a choice: should my code execute always, or should it execute only at the point where the one-time hook is used (and not at all if this is impossible)? For both of these possibilities there are use cases.

It is possible to nest this declaration using the same hook (or different hooks): e.g.,

`\AddToHookNext{<hook>}{<code-1>\AddToHookNext{<hook>}{<code-2>}}`

will execute `<code-1>` next time the `<hook>` is used and at that point puts `<code-2>` into the `<hook>` so that it gets executed on following time the hook is run.

A hook doesn’t have to exist for code to be added to it. This allows for hooks to work regardless of package loading order. See section 2.1.8.

The `<hook>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

**`\AddToHookNextWithArguments`**    `\AddToHookNextWithArguments {<hook>} {<code>}`

---

Works exactly like `\AddToHookNext`, but the `<code>` can contain references to the arguments of the `<hook>` as described for `\AddToHookWithArguments` above. Section 2.7 explains hooks with arguments.

The `<hook>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

**`\ClearHookNext`**    `\ClearHookNext {<hook>}`

---

Normally `\AddToHookNext` is only used when you know precisely where it will apply and why you want some extra code at that point. However, there are a few use cases in which such a declaration needs to be canceled, for example, when discarding a page with `\DiscardShipoutBox` (but even then not always), and in such situations `\ClearHookNext` can be used.

---

<sup>4</sup>There is no mechanism to reorder such code chunks (or delete them).

### 2.1.5 Hook names and default labels

It is best practice to use `\AddToHook` in packages or classes *without specifying a  $\langle label \rangle$*  because then the package or class name is automatically used, which is helpful if rules are needed, and avoids mistyping the  $\langle label \rangle$ .

Using an explicit  $\langle label \rangle$  is only necessary in very specific situations, e.g., if you want to add several chunks of code into a single hook and have them placed in different parts of the hook (by providing some rules).

The other case is when you develop a larger package with several sub-packages. In that case you may want to use the same  $\langle label \rangle$  throughout the sub-packages in order to avoid that the labels change if you internally reorganize your code.

Except for `\UseHook`, `\UseOneTimeHook` and `\IfHookEmptyTF` (and their `expl3` interfaces `\hook_use:n`, `\hook_use_once:n` and `\hook_if_empty:nTF`), all  $\langle hook \rangle$  and  $\langle label \rangle$  arguments are processed in the same way: first, spaces are trimmed around the argument, then it is fully expanded until only character tokens remain. If the full expansion of the  $\langle hook \rangle$  or  $\langle label \rangle$  contains a non-expandable non-character token, a low-level  $\TeX$  error is raised (namely, the  $\langle hook \rangle$  is expanded using  $\TeX$ 's `\csname...\endcsname`, as such, Unicode characters are allowed in  $\langle hook \rangle$  and  $\langle label \rangle$  arguments). The arguments of `\UseHook`, `\UseOneTimeHook`, and `\IfHookEmptyTF` are processed much in the same way except that spaces are not trimmed around the argument, for better performance.

It is not enforced, but highly recommended that the hooks defined by a package, and the  $\langle labels \rangle$  used to add code to other hooks contain the package name to easily identify the source of the code chunk and to prevent clashes. This should be the standard practice, so this hook management code provides a shortcut to refer to the current package in the name of a  $\langle hook \rangle$  and in a  $\langle label \rangle$ . If the  $\langle hook \rangle$  name or the  $\langle label \rangle$  consist just of a single dot (`.`), or starts with a dot followed by a slash (`./`) then the dot denotes the  $\langle default label \rangle$  (usually the current package or class name—see `\SetDefaultHookLabel`). A `“.”` or `“./”` anywhere else in a  $\langle hook \rangle$  or in  $\langle label \rangle$  is treated literally and is not replaced.

For example, inside the package `mypackage.sty`, the default label is `mypackage`, so the instructions:

```
\NewHook    {./hook}
\AddToHook {./hook}[.]{code}      % Same as \AddToHook{./hook}{code}
\AddToHook {./hook}[./sub]{code}
\DeclareHookRule{begindocument}{.}{before}{babel}
\AddToHook {file/foo.tex/after}{code}
```

are equivalent to:

```
\NewHook    {mypackage/hook}
\AddToHook {mypackage/hook}[mypackage]{code}
\AddToHook {mypackage/hook}[mypackage/sub]{code}
\DeclareHookRule{begindocument}{mypackage}{before}{babel}
\AddToHook {file/foo.tex/after}{code} % unchanged
```

The  $\langle default label \rangle$  is automatically set equal to the name of the current package or class at the time the package is loaded. If the hook command is used outside of a package, or the current file wasn't loaded with `\usepackage` or `\documentclass`, then the `top-level` is used as the  $\langle default label \rangle$ . This may have exceptions—see `\PushDefaultHookLabel`.

This syntax is available in all  $\langle label \rangle$  arguments and most  $\langle hook \rangle$  arguments, both in the L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> interface, and the L<sup>A</sup>T<sub>E</sub>X 3 interface described in section 2.2.

**Important:**

*The dot-syntax is **not** available with `\UseHook` and some other commands that are typically used within code!*

Note, however, that the replacement of `.` by the  $\langle default label \rangle$  takes place when the hook command is executed, so actions that are somehow executed after the package ends will have the wrong  $\langle default label \rangle$  if the dot-syntax is used. For that reason, this syntax is not available in `\UseHook` (and `\hook_use:n`) because the hook is most of the time used outside of the package file in which it was defined. This syntax is also not available in the hook conditionals `\IfHookEmptyTF` (and `\hook_if_empty:nTF`), because these conditionals are used in some performance-critical parts of the hook management code, and because they are usually used to refer to other package's hooks, so the dot-syntax doesn't make much sense.

In some cases, for example in large packages, one may want to separate the code in logical parts, but still use the main package name as the  $\langle label \rangle$ , then the  $\langle default label \rangle$  can be set using `\PushDefaultHookLabel{...}`...`\PopDefaultHookLabel` or `\SetDefaultHookLabel{...}`.

---

<code>\PushDefaultHookLabel</code>	<code>\PushDefaultHookLabel {<math>\langle default label \rangle</math>}</code>
<code>\PopDefaultHookLabel</code>	<code><math>\langle code \rangle</math></code>

---

`\PopDefaultHookLabel`

`\PushDefaultHookLabel` sets the current  $\langle default label \rangle$  to be used in  $\langle label \rangle$  arguments, or when replacing a leading “.” (see above). `\PopDefaultHookLabel` reverts the  $\langle default label \rangle$  to its previous value.

Inside a package or class, the  $\langle default label \rangle$  is equal to the package or class name, unless explicitly changed. Everywhere else, the  $\langle default label \rangle$  is `top-level` (see section 2.1.6) unless explicitly changed.

The effect of `\PushDefaultHookLabel` holds until the next `\PopDefaultHookLabel`. `\usepackage` (and `\RequirePackage` and `\documentclass`) internally use

```
\PushDefaultHookLabel{ $\langle package name \rangle$ }
 $\langle package code \rangle$ 
\PopDefaultHookLabel
```

to set the  $\langle default label \rangle$  for the package or class file. Inside the  $\langle package code \rangle$  the  $\langle default label \rangle$  can also be changed with `\SetDefaultHookLabel`. `\input` and other file input-related commands from the L<sup>A</sup>T<sub>E</sub>X kernel do not use `\PushDefaultHookLabel`, so code within files loaded by these commands does *not* get a dedicated  $\langle label \rangle$ ! (that is, the  $\langle default label \rangle$  is the current active one when the file was loaded.)

Packages that provide their own package-like interfaces (TikZ's `\usetikzlibrary`, for example) can use `\PushDefaultHookLabel` and `\PopDefaultHookLabel` to set dedicated labels and to emulate `\usepackage`-like hook behavior within those contexts.

The `top-level` label is treated differently, and is reserved to the user document, so it is not allowed to change the  $\langle default label \rangle$  to `top-level`.

---

<code>\SetDefaultHookLabel</code>	<code>\SetDefaultHookLabel {⟨default label⟩}</code>
-----------------------------------	---

---

Similarly to `\PushDefaultHookLabel`, sets the current `⟨default label⟩` to be used in `⟨label⟩` arguments, or when replacing a leading “.”. The effect holds until the label is changed again or until the next `\PopDefaultHookLabel`. The difference between `\PushDefaultHookLabel` and `\SetDefaultHookLabel` is that the latter does not save the current `⟨default label⟩`.

This command is useful when a large package is composed of several smaller packages, but all should have the same `⟨label⟩`, so `\SetDefaultHookLabel` can be used at the beginning of each package file to set the correct label.

`\SetDefaultHookLabel` is not allowed in the main document, where the `⟨default label⟩` is `top-level` and there is no `\PopDefaultHookLabel` to end its effect. It is also not allowed to change the `⟨default label⟩` to `top-level`.

### 2.1.6 The `top-level` label

The `top-level` label, assigned to code added from the main document, is different from other labels. Code added to hooks (usually `\AtBeginDocument`) in the preamble is almost always to change something defined by a package, so it should go at the very end of the hook.

Therefore, code added in the `top-level` is always executed at the end of the hook, regardless of where it was declared. If the hook is reversed (see `\NewReversedHook`), the `top-level` chunk is executed at the very beginning instead.

Rules regarding `top-level` have no effect: if a user wants to have a specific set of rules for a code chunk, they should use a different label to said code chunk, and provide a rule for that label instead.

The `top-level` label is exclusive for the user, so trying to add code with that label from a package results in an error.

### 2.1.7 Defining relations between hook code

The default assumption is that code added to hooks by different packages are independent and the order in which they are executed is irrelevant. While this is true in many cases it is obviously false in others.

Before the hook management system was introduced packages had to take elaborate precautions to determine whether some other package had also been loaded (before or after) and then to find some ways to alter its behavior accordingly. In addition it was often the user’s responsibility to load packages in the right order so that alterations made by packages were done in that same order; and in some cases even altering the loading order wouldn’t resolve the conflicts.

With the new hook management system it is now possible to define rules (i.e., relationships) between code chunks added by different packages and to specify explicitly the order in which they should be processed.

The rules can be declared for hooks before the hook has been declared with `\NewHook` and they are allowed to refer to code labels that do not yet exist, e.g., because a package defining the code chunk with that label has not yet been loaded. When the hook code is finally sorted for fast execution, all rules that apply are acted on and the others are ignored.

This offers the flexibility needed to handle complicated relationships between code from different packages and to set this up beforehand in a way that is independent of whether or not the packages are actually loaded in a specific document. The downside

of this is that misspellings of hook names or code labels will not raise any error, instead the rule will simply never apply!

---

**\DeclareHookRule** `\DeclareHookRule {<hook>} {<label1>} {<relation>} {<label2>}`

---

Defines a relation between `<label1>` and `<label2>` for a given `<hook>`. If `<hook>` is `??` this defines a default relation for all hooks that use the two labels, i.e., that have chunks of code labeled with `<label1>` and `<label2>`.

Currently, the supported relations are the following:

**before** or **<** Code for `<label1>` comes before code for `<label2>`.

**after** or **>** Code for `<label1>` comes after code for `<label2>`.

**incompatible-warning** Only code for either `<label1>` or `<label2>` can appear for that hook (a way to say that two packages—or parts of them—are incompatible). A warning is raised if both labels appear in the same hook.

**incompatible-error** Like **incompatible-warning** but instead of a warning a L<sup>A</sup>T<sub>E</sub>X error is raised, and the code for both labels are dropped from that hook until the conflict is resolved.

**voids** Code for `<label1>` overwrites code for `<label2>`. More precisely, code for `<label2>` is dropped for that hook. This can be used, for example if one package is a superset in functionality of another one and therefore wants to undo code in some hook and replace it with its own version.

**unrelated** The order of code for `<label1>` and `<label2>` is irrelevant. This rule is there to undo an incorrect rule specified earlier.

There can only be a single relation between two labels for a given hook, i.e., a later `\DeclareHookRule` overwrites any previous declaration. In all cases rules specific to a given hook take precedence over default rules that use `??` as the `<hook>`.

If a default rule is applied, it is done before reversing the label order in a reversed hook, e.g., **before** in a default rule effectively becomes **after** in such a hook. In contrast, a rule for a specific hook is always applied to the state after any reversal (i.e., the state you see when using `\ShowHook` on that hook).

The `<hook>` and `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

**\ClearHookRule** `\ClearHookRule {<hook>} {<label1>} {<label2>}`

---

Syntactic sugar for saying that `<label1>` and `<label2>` are unrelated for the given `<hook>`.

---

`\DeclareDefaultHookRule` `\DeclareDefaultHookRule {<label1>} {<relation>} {<label2>}`

---

This sets up a relation between `<label1>` and `<label2>` for all hooks unless overwritten by a specific rule for a hook. Useful for cases where one package has a specific relation to some other package, e.g., is `incompatible` or always needs a special ordering `before` or `after`. (Technically it is just a shorthand for using `\DeclareHookRule` with `??` as the hook name.)

If such a rule is applied to a reversed hook it behaves as if the rule is reversed (e.g., `after` becomes `before`) because those rules are applied first and then the order is reversed. The rationale is that in hook pairs (in which the ordering in one is reversed) default rules have to be reversed too in nearly all scenarios. If this is not the case, a default rule can't be used or has to be overwritten with an explicit `\DeclareHookRule` for that specific hook.

Declaring default rules is only supported in the document preamble.<sup>5</sup>

The `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

### 2.1.8 Querying hooks

Simpler data types, like token lists, have three possible states; they can:

- exist and be empty;
- exist and be non-empty; and
- not exist (in which case emptiness doesn't apply);

Hooks are a bit more complicated: a hook may exist or not, and independently it may or may not be empty. This means that even a hook that doesn't exist may be non-empty and it can also be disabled.

This seemingly strange state may happen when, for example, package *A* defines hook `A/foo`, and package *B* adds some code to that hook. However, a document may load package *B* before package *A*, or may not load package *A* at all. In both cases some code is added to hook `A/foo` without that hook being defined yet, thus that hook is said to be non-empty, whereas it doesn't exist. Therefore, querying the existence of a hook doesn't imply its emptiness, neither does the other way around.

Given that code or rules can be added to a hook even if it doesn't physically exist yet, means that a querying its existence has no real use case (in contrast to other variables that can only be update if they have already been declared). For that reason only the test for emptiness has a public interface.

A hook is said to be empty when no code was added to it, either to its permanent code pool, or to its “next” token list. The hook doesn't need to be declared to have code added to its code pool. A hook is said to exist when it was declared with `\NewHook` or some variant thereof. Generic hooks such as `file` and `env` hooks are automatically declared when code is added to them.

---

<sup>5</sup>Trying to do so, e.g., via `\DeclareHookRule` with `??` has bad side-effects and is not supported (though not explicitly caught for performance reasons).

---

<code>\IfHookEmptyTF</code>	★	<code>\IfHookEmptyTF {&lt;hook&gt;} {&lt;true code&gt;} {&lt;false code&gt;}</code>
<code>\IfHookEmptyT</code>	★	
<code>\IfHookEmptyF</code>	★	Tests if the <code>&lt;hook&gt;</code> is empty ( <i>i.e.</i> , no code was added to it using either <code>\AddToHook</code> or <code>\AddToHookNext</code> ) or such code was removed again (via <code>\RemoveFromHook</code> ), and branches to either <code>&lt;true code&gt;</code> or <code>&lt;false code&gt;</code> depending on the result.

---

The `<hook>` *cannot* be specified using the dot-syntax. A leading `.` is treated literally.

### 2.1.9 Displaying hook code

If one has to adjust the code execution in a hook using a hook rule it is helpful to get some information about the code associated with a hook, its current order and the existing rules.

---

<code>\ShowHook</code>	<code>\ShowHook {&lt;hook&gt;}</code>
<code>\LogHook</code>	<code>\LogHook {&lt;hook&gt;}</code>

---

Displays information about the `<hook>` such as

- the code chunks (and their labels) added to it,
- any rules set up to order them,
- the computed order in which the chunks are executed,
- any code executed on the next invocation only.

`\LogHook` prints the information to the `.log` file, and `\ShowHook` prints them to the terminal/command window and starts T<sub>E</sub>X's prompt (only in `\errorstopmode`) to wait for user action.

The `<hook>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

Suppose a hook `example-hook` whose output of `\ShowHook{example-hook}` is:

```

1  -> The hook 'example-hook':
2  > Code chunks:
3  >   foo -> [code from package 'foo']
4  >   bar -> [from package 'bar']
5  >   baz -> [package 'baz' is here]
6  > Document-level (top-level) code (executed last):
7  >   -> [code from 'top-level']
8  > Extra code for next invocation:
9  >   -> [one-time code]
10 > Rules:
11 >   foo|baz with relation >
12 >   baz|bar with default relation <
13 > Execution order (after applying rules):
14 >   baz, foo, bar.
```

In the listing above, lines 3 to 5 show the three code chunks added to the hook and their respective labels in the format

`<label> -> <code>`

Line 7 shows the code chunk added by the user in the main document (labeled `top-level`) in the format

```
Document-level (top-level) code (executed  $\langle first/last \rangle$ ):
->  $\langle top-level\ code \rangle$ 
```

This code will be either the first or last code executed by the hook (`last` if the hook is normal, `first` if it is reversed). This chunk is not affected by rules and does not take part in sorting.

Line 9 shows the code chunk for the next execution of the hook in the format

```
->  $\langle next-code \rangle$ 
```

This code will be used and disappear at the next `\UseHook{example-hook}`, in contrast to the chunks mentioned earlier, which can only be removed from that hook by doing `\RemoveFromHook{<label>}[example-hook]`.

Lines 11 and 12 show the rules declared that affect this hook in the format

```
 $\langle label-1 \rangle | \langle label-2 \rangle$  with  $\langle default? \rangle$  relation  $\langle relation \rangle$ 
```

which means that the  $\langle relation \rangle$  applies to  $\langle label-1 \rangle$  and  $\langle label-2 \rangle$ , in that order, as detailed in `\DeclareHookRule`. If the relation is `default` it means that this rule applies to  $\langle label-1 \rangle$  and  $\langle label-2 \rangle$  in *all* hooks, (unless overridden by a non-default relation).

Finally, line 14 lists the labels in the hook after sorting; that is, in the order they will be executed when the hook is used.

### 2.1.10 Debugging hook code

---

```
\DebugHooksOn \DebugHooksOn ... \DebugHooksOff
\DebugHooksOff
```

---

Turn the debugging of hook code on or off. This displays most changes made to the hook data structures. The output is rather coarse and not really intended for normal use, but it can be helpful in case hooks do not work as expected. See also [2.1.9](#) for commands to inspect individual hooks.

## 2.2 L3 programming layer (expl3) interfaces

This is a quick summary of the L<sup>A</sup>T<sub>E</sub>X3 programming interfaces for use with packages written in `expl3`. In contrast to the L<sup>A</sup>T<sub>E</sub>X<sub>2 $\epsilon$</sub>  interfaces they always use mandatory arguments only, e.g., you always have to specify the  $\langle label \rangle$  for a code chunk. We therefore suggest to use the declarations discussed in the previous section even in `expl3` packages, but the choice is yours.

---

```
\hook_new:n \hook_new:n {<hook>}
\hook_new_reversed:n \hook_new_reversed:n {<hook>}
\hook_new_pair:nn \hook_new_pair:nn {<hook-1>} {<hook-2>}
```

---

Creates a new  $\langle hook \rangle$  with normal or reverse ordering of code chunks. `\hook_new_pair:nn` creates a pair of such hooks with  $\{<hook-2>\}$  being a reversed hook. If a hook name is already taken, an error is raised and the hook is not created.

The  $\langle hook \rangle$  can be specified using the dot-syntax to denote the current package name. See section [2.1.5](#).

<hr/> <hr/>	<code>\hook_new_with_args:nn</code>	<code>\hook_new_with_args:nn {\langle hook \rangle} {\langle number \rangle}</code>
<hr/>	<code>\hook_new_reversed_with_args:nn</code>	<code>\hook_new_reversed_with_args:nn {\langle hook \rangle} {\langle number \rangle}</code>
<hr/>	<code>\hook_new_pair_with_args:nnn</code>	<code>\hook_new_pair_with_args:nnn {\langle hook-1 \rangle} {\langle hook-2 \rangle} {\langle number \rangle}</code>

Creates a new  $\langle hook \rangle$  with normal or reverse ordering of code chunks, that takes  $\langle number \rangle$  arguments from the input stream when it is used. `\hook_new_pair_with_args:nn` creates a pair of such hooks with  $\{\langle hook-2 \rangle\}$  being a reversed hook. If a hook name is already taken, an error is raised and the hook is not created.

The  $\langle hook \rangle$  can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

<hr/> <hr/>	<code>\hook_disable_generic:n</code>	<code>\hook_disable_generic:n {\langle hook \rangle}</code>
-------------	--------------------------------------	---

Marks  $\{\langle hook \rangle\}$  as disabled. Any further attempt to add code to it or declare it, will result in an error and any call to `\hook_use:n` will simply do nothing.

This declaration is intended for use with generic hooks that are known not to work (see `lthcmdhooks-doc`) if they receive code.

The  $\langle hook \rangle$  can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

<hr/> <hr/>	<code>\hook_activate_generic:n</code>	<code>\hook_activate_generic:n {\langle hook \rangle}</code>
-------------	---------------------------------------	--

This is like `\hook_new:n` but it does nothing if the hook was previously declared with `\hook_new:n`. This declaration should be used only in special situations, e.g., when a command from another package needs to be altered and it is not clear whether a generic cmd hook (for that command) has been previously explicitly declared.

Normally `\hook_new:n` should be used instead of this.

<hr/> <hr/>	<code>\hook_use:n</code>	<code>\hook_use:n {\langle hook \rangle}</code>
<hr/>	<code>\hook_use:nnw</code>	<code>\hook_use:nnw {\langle hook \rangle} {\langle number \rangle} {\langle arg_1 \rangle} \dots {\langle arg_n \rangle}</code>

Executes the  $\{\langle hook \rangle\}$  code followed (if set up) by the code for next invocation only, then empties that next invocation code. `\hook_use:nnw` should be used for hooks declared with arguments, and should be followed by as many brace groups as the declared number of arguments. The  $\langle number \rangle$  should be the number of arguments declared for the hook. If the hook is not declared, this command does nothing and it will remove  $\langle number \rangle$  items from the input.

The  $\langle hook \rangle$  *cannot* be specified using the dot-syntax. A leading . is treated literally.

<hr/> <hr/>	<code>\hook_use_once:n</code>	<code>\hook_use_once:n {\langle hook \rangle}</code>
<hr/>	<code>\hook_use_once:nnw</code>	<code>\hook_use_once:nnw {\langle hook \rangle} {\langle number \rangle} {\langle arg_1 \rangle} \dots {\langle arg_n \rangle}</code>

Changes the  $\{\langle hook \rangle\}$  status so that from now on any addition to the hook code is executed immediately. Then execute any  $\{\langle hook \rangle\}$  code already set up. `\hook_use_once:nnw` should be used for hooks declared with arguments, and should be followed by as many brace groups as the declared number of arguments. The  $\langle number \rangle$  should be the number of arguments declared for the hook. If the hook is not declared, this command does nothing and it will remove  $\langle number \rangle$  items from the input.

The  $\langle hook \rangle$  *cannot* be specified using the dot-syntax. A leading . is treated literally.

<hr/> <hr/>	<code>\hook_gput_code:nnn</code>	<code>\hook_gput_code:nnn {\langle hook \rangle} {\langle label \rangle} {\langle code \rangle}</code>
-------------	----------------------------------	--

---

<code>\hook_gput_code_with_args:nnn</code>	<code>\hook_gput_code_with_args:nnn {&lt;hook&gt;} {&lt;label&gt;} {&lt;code&gt;}</code>
--	--

---

Adds a chunk of `<code>` to the `<hook>` labeled `<label>`. If the label already exists the `<code>` is appended to the already existing code.

If `\hook_gput_code_with_args:nnn` is used, the `<code>` can access the arguments passed to `\hook_use:nnw` (or `\hook_use_once:nnw`) with `#1`, `#2`, ..., `#n` (up to the number of arguments declared for the hook). In that case, if an actual parameter token should be added to the code, it should be doubled.

If code is added to an external `<hook>` (of the kernel or another package) then the convention is to use the package name as the `<label>` not some internal module name or some other arbitrary string.

The `<hook>` and `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\hook_gput_next_code:nn</code>	<code>\hook_gput_next_code:nn {&lt;hook&gt;} {&lt;code&gt;}</code>
--------------------------------------	--

---

<code>\hook_gput_next_code_with_args:nn</code>	<code>\hook_gput_next_code_with_args:nn {&lt;hook&gt;} {&lt;code&gt;}</code>
--	--

---

Adds a chunk of `<code>` for use only in the next invocation of the `<hook>`. Once used it is gone.

If `\hook_gput_next_code_with_args:nn` is used, the `<code>` can access the arguments passed to `\hook_use:nnw` (or `\hook_use_once:nnw`) with `#1`, `#2`, ..., `#n` (up to the number of arguments declared for the hook). In that case, if an actual parameter token should be added to the code, it should be doubled.

This is simpler than `\hook_gput_code:nnn`, the code is simply appended to the hook in the order of declaration at the very end, i.e., after all standard code for the hook got executed. Thus if one needs to undo what the standard does one has to do that as part of `<code>`.

The `<hook>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\hook_gclear_next_code:n</code>	<code>\hook_gclear_next_code:n {&lt;hook&gt;}</code>
---------------------------------------	--

---

Undo any earlier `\hook_gput_next_code:nn`.

---

<code>\hook_gremove_code:nn</code>	<code>\hook_gremove_code:nn {&lt;hook&gt;} {&lt;label&gt;}</code>
------------------------------------	---

---

Removes any code for `<hook>` labeled `<label>`.

If there is no code under the `<label>` in the `<hook>`, or if the `<hook>` does not exist, a warning is issued when you attempt to use `\hook_gremove_code:nn`, and the command is ignored.

If the second argument is `*`, then all code chunks are removed. This is rather dangerous as it drops code from other packages one may not know about, so think twice before using that!

The `<hook>` and `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\hook_gset_rule:nnnn</code>	<code>\hook_gset_rule:nnnn {&lt;hook&gt;} {&lt;label1&gt;} {&lt;relation&gt;} {&lt;label2&gt;}</code>
-----------------------------------	---

---

Relate `<label1>` with `<label2>` when used in `<hook>`. See `\DeclareHookRule` for the allowed `<relation>`s. If `<hook>` is ?? a default rule is specified.

The `<hook>` and `<label>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5. The dot-syntax is parsed in both `<label>` arguments, but it usually makes sense to be used in only one of them.

---

<code>\hook_if_empty_p:n *</code>	<code>\hook_if_empty:nTF {&lt;hook&gt;} {&lt;true code&gt;} {&lt;false code&gt;}</code>
<code>\hook_if_empty:nTF *</code>	Tests if the <code>&lt;hook&gt;</code> is empty ( <i>i.e.</i> , no code was added to it using either <code>\AddToHook</code> or <code>\AddToHookNext</code> ), and branches to either <code>&lt;true code&gt;</code> or <code>&lt;false code&gt;</code> depending on the result.

---

The `<hook>` *cannot* be specified using the dot-syntax. A leading `.` is treated literally.

---

<code>\hook_show:n</code>	<code>\hook_show:n {&lt;hook&gt;}</code>
<code>\hook_log:n</code>	<code>\hook_log:n {&lt;hook&gt;}</code>

---

Displays information about the `<hook>` such as

- the code chunks (and their labels) added to it,
- any rules set up to order them,
- the computed order in which the chunks are executed,
- any code executed on the next invocation only.

`\hook_log:n` prints the information to the `.log` file, and `\hook_show:n` prints them to the terminal/command window and starts T<sub>E</sub>X's prompt (only if `\errorstopmode`) to wait for user action.

The `<hook>` can be specified using the dot-syntax to denote the current package name. See section 2.1.5.

---

<code>\hook_debug_on:</code>	<code>\hook_debug_on:</code>
<code>\hook_debug_off:</code>	Turns the debugging of hook code on or off. This displays changes to the hook data.

---

## 2.3 On the order of hook code execution

Chunks of code for a `<hook>` under different labels are supposed to be independent if there are no special rules set up that define a relation between the chunks. This means that you can't make assumptions about the order of execution!

Suppose you have the following declarations:

```
\NewHook{myhook}
\AddToHook{myhook}[packageA]{\typeout{A}}
\AddToHook{myhook}[packageB]{\typeout{B}}
\AddToHook{myhook}[packageC]{\typeout{C}}
```

then executing the hook with `\UseHook` will produce the `\typeout` A B C in that order. In other words, the execution order is computed to be `packageA`, `packageB`, `packageC` which you can verify with `\ShowHook{myhook}`:

```
-> The hook 'myhook':
> Code chunks:
>   packageA -> \typeout {A}
>   packageB -> \typeout {B}
>   packageC -> \typeout {C}
> Document-level (top-level) code (executed last):
>   ---
> Extra code for next invocation:
```

```

> ---
> Rules:
> ---
> Execution order:
>   packageA, packageB, packageC.

```

The reason is that the code chunks are internally saved in a property list and the initial order of such a property list is the order in which key-value pairs got added. However, that is only true if nothing other than adding happens!

Suppose, for example, you want to replace the code chunk for `packageA`, e.g.,

```

\RemoveFromHook{myhook}[packageA]
\AddToHook{myhook}[packageA]{\typeout{A alt}}

```

then your order becomes `packageB`, `packageC`, `packageA` because the label got removed from the property list and then re-added (at its end).

While that may not be too surprising, the execution order is also sometimes altered if you add a redundant rule, e.g. if you specify

```

\DeclareHookRule{myhook}{packageA}{before}{packageB}

```

instead of the previous lines we get

```

-> The hook 'myhook':
> Code chunks:
>   packageA -> \typeout {A}
>   packageB -> \typeout {B}
>   packageC -> \typeout {C}
> Document-level (top-level) code (executed last):
>   ---
> Extra code for next invocation:
>   ---
> Rules:
>   packageB|packageA with relation >
> Execution order (after applying rules):
>   packageA, packageC, packageB.

```

As you can see the code chunks are still in the same order, but in the execution order for the labels `packageB` and `packageC` have swapped places. The reason is that, with the rule there are two orders that satisfy it, and the algorithm for sorting happened to pick a different one compared to the case without rules (where it doesn't run at all as there is nothing to resolve). Incidentally, if we had instead specified the redundant rule

```

\DeclareHookRule{myhook}{packageB}{before}{packageC}

```

the execution order would not have changed.

In summary: it is not possible to rely on the order of execution unless there are rules that partially or fully define the order (in which you can rely on them being fulfilled).

## 2.4 The use of “reversed” hooks

You may have wondered why you can declare a “reversed” hook with `\NewReversedHook` and what that does exactly.

In short: the execution order of a reversed hook (without any rules!) is exactly reversed to the order you would have gotten for a hook declared with `\NewHook`.

This is helpful if you have a pair of hooks where you expect to see code added that involves grouping, e.g., starting an environment in the first and closing that environment in the second hook. To give a somewhat contrived example<sup>6</sup>, suppose there is a package adding the following:

```
\AddToHook{env/quote/before}[package-1]{\begin{itshape}}
\AddToHook{env/quote/after} [package-1]{\end{itshape}}
```

As a result, all quotes will be in italics. Now suppose further that another `package-too` makes the quotes also in blue and therefore adds:

```
\usepackage{color}
\AddToHook{env/quote/before}[package-too]{\begin{color}{blue}}
\AddToHook{env/quote/after} [package-too]{\end{color}}
```

Now if the `env/quote/after` hook would be a normal hook we would get the same execution order in both hooks, namely:

```
package-1, package-too
```

(or vice versa) and as a result, would get:

```
\begin{itshape}\begin{color}{blue} ...
\end{itshape}\end{color}
```

and an error message saying that `\begin{color}` was ended by `\end{itshape}`. With `env/quote/after` declared as a reversed hook the execution order is reversed and so all environments are closed in the correct sequence and `\ShowHook` would give us the following output:

```
-> The hook 'env/quote/after':
> Code chunks:
>   package-1 -> \end {itshape}
>   package-too -> \end {color}
> Document-level (top-level) code (executed first):
>   ---
> Extra code for next invocation:
>   ---
> Rules:
>   ---
> Execution order (after reversal):
>   package-too, package-1.
```

If there is a matching default rule (done with `\DeclareDefaultHookRule` or with `??` for the hook name) then this default rule is applied before the reversal so that the order in the reversed hook mirrors the one in the normal hook. However, all rules specific to a hook happen always after the reversal of the execution order, so if you alter the order you will probably have to alter it in both hooks, not just in one, but that depends on the use case.

---

<sup>6</sup>There are simpler ways to achieve the same effect.

## 2.5 Difference between “normal” and “one-time” hooks

When executing a hook a developer has the choice of using either `\UseHook` or `\UseOneTimeHook` (or their `expl3` equivalents `\hook_use:n` and `\hook_use_once:n`). This choice affects how `\AddToHook` is handled after the hook has been executed for the first time.

With normal hooks adding code via `\AddToHook` means that the code chunk is added to the hook data structure and then used each time `\UseHook` is called.

With one-time hooks it this is handled slightly differently: After `\UseOneTimeHook` has been called, any further attempts to add code to the hook via `\AddToHook` will simply execute the `<code>` immediately.

This has some consequences one needs to be aware of:

- If `<code>` is added to a normal hook after the hook was executed and it is never executed again for one or the other reason, then this new `<code>` will never be executed.
- In contrast if that happens with a one-time hook the `<code>` is executed immediately.

In particular this means that construct such as

```
\AddToHook{myhook}  
{ <code-1> \AddToHook{myhook}{<code-2>} <code-3> }
```

works for one-time hooks<sup>7</sup> (all three code chunks are executed one after another), but it makes little sense with a normal hook, because with a normal hook the first time `\UseHook{myhook}` is executed it would

- execute `<code-1>`,
- then execute `\AddToHook{myhook}{code-2}` which adds the code chunk `<code-2>` to the hook for use on the next invocation,
- and finally execute `<code-3>`.

The second time `\UseHook` is called it would execute the above and in addition `<code-2>` as that was added as a code chunk to the hook in the meantime. So each time the hook is used another copy of `<code-2>` is added and so that code chunk is executed `<# of invocations> - 1` times.

## 2.6 Generic hooks provided by packages

The hook management system also implements a category of hooks that are called “Generic Hooks”. Normally a hook has to be explicitly declared before it can be used in code. This ensures that different packages are not using the same hook name for unrelated purposes—something that would result in absolute chaos. However, there are a number of “standard” hooks where it is unreasonable to declare them beforehand, e.g., each and every command has (in theory) an associated **before** and **after** hook. In such cases, i.e., for command, environment or file hooks, they can be used simply by adding code to them with `\AddToHook`. For more specialized generic hooks, e.g., those provided

---

<sup>7</sup>This is sometimes used with `\AtBeginDocument` which is why it is supported.

by `babel`, you have to additionally enable them with `\ActivateGenericHook` as explained below.

The generic hooks provided by  $\text{\LaTeX}$  are those for `cmd`, `env`, `file`, `include`, `package`, and `class`, and all these are available out of the box: you only have to use `\AddToHook` to add code to them, but you don't have to add `\UseHook` or `\UseOneTimeHook` to your code, because this is already done for you (or, in the case of `cmd` hooks, the command's code is patched at `\begin{document}`, if necessary).

However, if you want to provide further generic hooks in your own code, the situation is slightly different. To do this you should use `\UseHook` or `\UseOneTimeHook`, but *without declaring the hook* with `\NewHook`. As mentioned earlier, a call to `\UseHook` with an undeclared hook name does nothing. So as an additional setup step, you need to explicitly activate your generic hook. Note that a generic hook produced in this way is always a normal hook.

For a truly generic hook, with a variable part in the hook name, such upfront activation would be difficult or impossible, because you typically do not know what kind of variable parts may come up in real documents.

For example, `babel` provides hooks such as `babel/⟨language⟩/afterextras`. However, language support in `babel` is often done through external language packages. Thus doing the activation for all languages inside the core `babel` code is not a viable approach. Instead it needs to be done by each language package (or by the user who wants to use a particular hook).

Because the hooks are not declared with `\NewHook` their names should be carefully chosen to ensure that they are (likely to be) unique. Best practice is to include the package or command name, as was done in the `babel` example above.

Generic hooks defined in this way are always normal hooks (i.e., you can't implement reversed hooks this way). This is a deliberate limitation, because it speeds up the processing considerably.

## 2.7 Hooks with arguments

Sometimes it is necessary to pass contextual information to a hook, and, for one reason or another, it is not feasible to store such information in macros. To serve this purpose, hooks can be declared with arguments, so that the programmer can pass along the data necessary for the code in the hook to function properly.

A hook with arguments works mostly like a regular hook, and most commands that work for regular hooks, also work for hooks that take arguments. The differences are when the hook is declared (`\NewHookWithArguments` is used instead of `\NewHook`), then code can be added with both `\AddToHook` and `\AddToHookWithArguments`, and when the hook is used (`\UseHookWithArguments` instead of `\UseHook`).

A hook with arguments must be declared as such (before it is first used, as all regular hooks) using `\NewHookWithArguments{⟨hook⟩}{⟨number⟩}`. All code added to that hook can then use `#1` to access the first argument, `#2` to access the second, and so forth up to the number of arguments declared. However, it is still possible to add code with references to the arguments of a hook that was not yet declared (we will discuss that later). At their core, hooks are macros, so  $\text{\TeX}$ 's limit of 9 arguments applies, and a low-level  $\text{\TeX}$  error is raised if you try to reference an argument number that doesn't exist.

To use a hook with arguments, just write `\UseHookWithArguments{<hook>}{<number>}` followed by a braced list of the arguments. For example, if the hook `test` takes three arguments, write:

```
\UseHookWithArguments{test}{3}{arg-1}{arg-2}{arg-3}
```

then, in the `<code>` of the hook, all instances of `#1` will be replaced by `arg-1`, `#2` by `arg-2` and so on. If, at the point of usage, the programmer provides more arguments than the hook is declared to take, the excess arguments are simply ignored by the hook. Behavior is unpredictable<sup>8</sup> if too few arguments are provided. If the hook isn't declared, `<number>` arguments are removed from the input stream.

Adding code to a hook with arguments can be done with `\AddToHookWithArguments` as well as with the regular `\AddToHook`, to achieve different outcomes. The main difference when it comes to adding code to a hook, in this case, is firstly the possibility of accessing a hook's arguments, of course, and second, how parameter tokens (`#6`) are treated.

Using `\AddToHook` in a hook that takes arguments will work as it does for all other hooks. This allows a package developer to add arguments to a hook that otherwise had none without having to worry about compatibility. This means that, for example:

```
\AddToHook{test}{\def\foo#1{Hello, #1!}}
```

will define the same macro `\foo` regardless if the hook `test` takes arguments or not.

Using `\AddToHookWithArguments` allows the `<code>` added to access the arguments of the hook with `#1`, `#2`, and so forth, up to the number of the arguments declared in the hook. This means that if one wants to add a `#6` to the `<code>` that token must be doubled in the input. The same definition from above, using `\AddToHookWithArguments`, needs to be rewritten:

```
\AddToHookWithArguments{test}{\def\foo##1{Hello, ##1!}}
```

Extending the above example to use the hook arguments, we could rewrite something like (now from declaration to usage, to get the whole picture):

```
\NewHookWithArguments{test}{1}
\AddToHookWithArguments{test}{%
  \typeout{Defining foo with "#1"}
  \def\foo##1{Hello, ##1! Some text after: #1}%
}
\UseHook{test}{Howdy!}
\ShowCommand\foo
```

Running the code above prints in the terminal:

```
Defining foo with "Howdy!"
> \foo=macro:
#1->Hello, #1! Some text after: Howdy!.
```

---

<sup>8</sup>The hook *will* take the declared number of arguments, and what will happen depends on what was grabbed, and what the hook code does with its arguments.

Note how `##1` in the call to `\AddToHookWithArguments` became `#1`, and the `#1` was replaced by the argument passed to the hook. Should the hook be used again, with a different argument, the definition would naturally change.

It is possible to add code referencing a hook’s arguments before such hook is declared and the number of hooks is fixed. However, if some code is added to the hook, that references more arguments than will be declared for the hook, there will be a low-level `TeX` error about an “Illegal parameter number” at the time the hook is declared, which will be hard to track down because at that point `TeX` can’t know whence the offending code came from. Thus it is important that package writers explicitly document how many arguments (if any) each hook can take, so users of those packages know how many arguments can be referenced, and equally important, what each argument means.

## 2.8 Private `LaTeX` kernel hooks

There are a few places where it is absolutely essential for `LaTeX` to function correctly that code is executed in a precisely defined order. Even that could have been implemented with the hook management (by adding various rules to ensure the appropriate ordering with respect to other code added by packages). However, this makes every document unnecessary slow, because there has to be sorting even though the result is predetermined. Furthermore it forces package writers to unnecessarily add such rules if they add further code to the hook (or break `LaTeX`).

For that reason such code is not using the hook management, but instead private kernel commands directly before or after a public hook with the following naming convention: `\@kernel@before@hook` or `\@kernel@after@hook`. For example, in `\enddocument` you find

```
\UseHook{enddocument}%
\@kernel@after@enddocument
```

which means first the user/package-accessible `enddocument` hook is executed and then the internal kernel hook. As their name indicates these kernel commands should not be altered by third-party packages, so please refrain from that in the interest of stability and instead use the public hook next to it.<sup>9</sup>

## 2.9 Legacy `LaTeX 2ε` interfaces

`LaTeX 2ε` offered a small number of hooks together with commands to add to them. They are listed here and are retained for backwards compatibility.

With the new hook management, several additional hooks have been added to `LaTeX` and more will follow. See the next section for what is already available.

---

<sup>9</sup>As with everything in `TeX` there is not enforcement of this rule, and by looking at the code it is easy to find out how the kernel adds to them. The main reason of this section is therefore to say “please don’t do that, this is unconfigurable code!”

---

<code>\AtBeginDocument</code>	<code>\AtBeginDocument [<i>&lt;label&gt;</i>] {<i>&lt;code&gt;</i>}</code>
-------------------------------	--

---

If used without the optional argument *<label>*, it works essentially like before, i.e., it is adding *<code>* to the hook `begindocument` (which is executed inside `\begin{document}`). However, all code added this way is labeled with the label `top-level` (see section 2.1.6) if done outside of a package or class or with the package/class name if called inside such a file (see section 2.1.5).

This way one can add code to the hook using `\AddToHook` or `\AtBeginDocument` using a different label and explicitly order the code chunks as necessary, e.g., run some code before or after another package's code. When using the optional argument the call is equivalent to running `\AddToHook {begindocument} [<label>] {<code>}`.

`\AtBeginDocument` is a wrapper around the `begindocument` hook (see section 3.2), which is a one-time hook. As such, after the `begindocument` hook is executed at `\begin{document}` any attempt to add *<code>* to this hook with `\AtBeginDocument` or with `\AddToHook` will cause that *<code>* to execute immediately instead. See section 2.5 for more on one-time hooks.

For important packages with known order requirement we may over time add rules to the kernel (or to those packages) so that they work regardless of the loading-order in the document.

---

<code>\AtEndDocument</code>	<code>\AtEndDocument [<i>&lt;label&gt;</i>] {<i>&lt;code&gt;</i>}</code>
-----------------------------	--

---

Like `\AtBeginDocument` but for the `enddocument` hook.

The few hooks that existed previously in L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> used internally commands such as `@begindocumenthook` and packages sometimes augmented them directly rather than working through `\AtBeginDocument`. For that reason there is currently support for this, that is, if the system detects that such an internal legacy hook command contains code it adds it to the new hook system under the label `legacy` so that it doesn't get lost.

However, over time the remaining cases of direct usage need updating because in one of the future release of L<sup>A</sup>T<sub>E</sub>X we will turn this legacy support off, as it does unnecessary slow down the processing.

### 3 L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> commands and environments augmented by hooks

In this section we describe the standard hooks that are now offered by L<sup>A</sup>T<sub>E</sub>X, or give pointers to other documents in which they are described. This section will grow over time (and perhaps eventually move to `usrguide3`).

#### 3.1 Generic hooks

As stated earlier, with the exception of generic hooks, all hooks must be declared with `\NewHook` before they can be used. All generic hooks have names of the form “*<type>/<name>/<position>*”, where *<type>* is from the predefined list shown below, and *<name>* is the variable part whose meaning will depend on the *<type>*. The last component, *<position>*, has more complex possibilities: it can always be `before` or `after`; for `env` hooks, it can also be `begin` or `end`; and for `include` hooks it can also be `end`. Each specific hook is documented below, or in `lthooks-doc.pdf` or `ltfilehook-doc.pdf`.

The generic hooks provided by L<sup>A</sup>T<sub>E</sub>X belong to one of the six types:

- env** Hooks executed before and after environments –  $\langle name \rangle$  is the name of the environment, and available values for  $\langle position \rangle$  are **before**, **begin**, **end**, and **after**;
- cmd** Hooks added to and executed before and after commands –  $\langle name \rangle$  is the name of the command, and available values for  $\langle position \rangle$  are **before** and **after**;
- file** Hooks executed before and after reading a file –  $\langle name \rangle$  is the name of the file (with extension), and available values for  $\langle position \rangle$  are **before** and **after**;
- package** Hooks executed before and after loading packages –  $\langle name \rangle$  is the name of the package, and available values for  $\langle position \rangle$  are **before** and **after**;
- class** Hooks executed before and after loading classes –  $\langle name \rangle$  is the name of the class, and available values for  $\langle position \rangle$  are **before** and **after**;
- include** Hooks executed before and after `\included` files –  $\langle name \rangle$  is the name of the included file (without the `.tex` extension), and available values for  $\langle position \rangle$  are **before**, **end**, and **after**.

Each of the hooks above are detailed in the following sections and in linked documentation.

### 3.1.1 Generic hooks for all environments

Every environment  $\langle env \rangle$  has now four associated hooks coming with it:

- env/ $\langle env \rangle$ /before** This hook is executed as part of `\begin` as the very first action, in particular prior to starting the environment group. Its scope is therefore not restricted by the environment.
- env/ $\langle env \rangle$ /begin** This hook is executed as part of `\begin` directly in front of the code specific to the environment start (e.g., the third argument of `\NewDocumentEnvironment` and the second argument of `\newenvironment`). Its scope is the environment body.
- env/ $\langle env \rangle$ /end** This hook is executed as part of `\end` directly in front of the code specific to the end of the environment (e.g., the forth argument of `\NewDocumentEnvironment` and the third argument of `\newenvironment`).
- env/ $\langle env \rangle$ /after** This hook is executed as part of `\end` after the code specific to the environment end and after the environment group has ended. Its scope is therefore not restricted by the environment.  
  
The hook is implemented as a reversed hook so if two packages add code to **env/ $\langle env \rangle$ /before** and to **env/ $\langle env \rangle$ /after** they can add surrounding environments and the order of closing them happens in the right sequence.

Given that these generic hook names involve `/` as part of their name they would not work if one tries to define an environment using a name that involves a `/`.<sup>10</sup>

Generic environment hooks are never one-time hooks even with environments that are supposed to appear only once in a document.<sup>11</sup> In contrast to other hooks there is also no need to declare them using `\NewHook`.

<sup>10</sup>Officially, L<sup>A</sup>T<sub>E</sub>X names for environments should only consist of a sequence of letters, numbers, and the character `*`, i.e., this is not a new restriction.

<sup>11</sup>Thus if one adds code to such hooks after the environment has been processed, it will only be executed if the environment appears again and if that doesn't happen the code will never get executed.

The hooks are only executed if `\begin{env}` and `\end{env}` is used. If the environment code is executed via low-level calls to `\env` and `\endenv` (e.g., to avoid the environment grouping) they are not available. If you want them available in code using this method, you would need to add them yourself, i.e., write something like

```
\UseHook{env/quote/before}\quote
...
\endquote\UseHook{env/quote/after}
```

to add the outer hooks, etc.

Largely for compatibility with existing packages, the following four commands are also available to set the environment hooks; but for new packages we recommend directly using the hook names and `\AddToHook`.

---

---

<code>\BeforeBeginEnvironment</code>	<code>\BeforeBeginEnvironment</code> [ <i>label</i> ] { <i>env</i> } { <i>code</i> }
--------------------------------------	--

This declaration adds to the `env/⟨env⟩/before` hook using the *label*. If *label* is not given, the *default label* is used (see section 2.1.5).

---

---

<code>\AtBeginEnvironment</code>	<code>\AtBeginEnvironment</code> [ <i>label</i> ] { <i>env</i> } { <i>code</i> }
----------------------------------	--

This is like `\BeforeBeginEnvironment` but it adds to the `env/⟨env⟩/begin` hook.

---

---

<code>\AtEndEnvironment</code>	<code>\AtEndEnvironment</code> [ <i>label</i> ] { <i>env</i> } { <i>code</i> }
--------------------------------	--

This is like `\BeforeBeginEnvironment` but it adds to the `env/⟨env⟩/end` hook.

---

---

<code>\AfterEndEnvironment</code>	<code>\AfterEndEnvironment</code> [ <i>label</i> ] { <i>env</i> } { <i>code</i> }
-----------------------------------	---

This is like `\BeforeBeginEnvironment` but it adds to the `env/⟨env⟩/after` hook.

### 3.1.2 Generic hooks for commands

Similar to environments there are now (at least in theory) two generic hooks available for any  $\text{\LaTeX}$  command. These are

**cmd/⟨name⟩/before** This hook is executed at the very start of the command execution.

**cmd/⟨name⟩/after** This hook is executed at the very end of the command body. It is implemented as a reversed hook.

In practice there are restrictions and especially the **after** hook works only with a subset of commands. Details about these restrictions are documented in `ltxcmdhooks-doc.pdf` or with code in `ltxcmdhooks-code.pdf`.

### 3.1.3 Generic hooks provided by file loading operations

There are several hooks added to  $\text{\LaTeX}$ 's process of loading file via its high-level interfaces such as `\input`, `\include`, `\usepackage`, `\RequirePackage`, etc. These are documented in `ltfilehook-doc.pdf` or with code in `ltfilehook-code.pdf`.

### 3.2 Hooks provided by `\begin{document}`

Until 2020 `\begin{document}` offered exactly one hook that one could add to using `\AtBeginDocument`. Experiences over the years have shown that this single hook in one place was not enough and as part of adding the general hook management system a number of additional hooks have been added at this point. The places for these hooks have been chosen to provide the same support as offered by external packages, such as `etoolbox` and others that augmented `\document` to gain better control.

Supported are now the following hooks (all of them one-time hooks):

**`begindocument/before`** This hook is executed at the very start of `\document`, one can think of it as a hook for code at the end of the preamble section and this is how it is used by `etoolbox`'s `\AtEndPreamble`.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

**`begindocument`** This hook is added to by using `\AddToHook{begindocument}` or by using `\AtBeginDocument` and it is executed after the `.aux` file has been read and most initialization are done, so they can be altered and inspected by the hook code. It is followed by a small number of further initializations that shouldn't be altered and are therefore coming later.

The hook should not be used to add material for typesetting as we are still in  $\text{\LaTeX}$ 's initialization phase and not in the document body. If such material needs to be added to the document body use the next hook instead.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

**`begindocument/end`** This hook is executed at the end of the `\document` code in other words at the beginning of the document body. The only command that follows it is `\ignorespaces`.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

The generic hooks executed by `\begin` also exist, i.e., `env/document/before` and `env/document/begin`, but with this special environment it is better use the dedicated one-time hooks above.

### 3.3 Hooks provided by `\end{document}`

$\text{\LaTeX 2}_{\epsilon}$  has always provided `\AtEndDocument` to add code to the `\end{document}`, just in front of the code that is normally executed there. While this was a big improvement over the situation in  $\text{\LaTeX 2.09}$ , it was not flexible enough for a number of use cases and so packages, such as `etoolbox`, `atveryend` and others patched `\enddocument` to add additional points where code could be hooked into.

Patching using packages is always problematical as leads to conflicts (code availability, ordering of patches, incompatible patches, etc.). For this reason a number of additional hooks have been added to the `\enddocument` code to allow packages to add code in various places in a controlled way without the need for overwriting or patching the core code.

Supported are now the following hooks (all of them one-time hooks):

**enddocument** The hook associated with `\AtEndDocument`. It is immediately called at the beginning of `\enddocument`.

When this hook is executed there may be still unprocessed material (e.g., floats on the deferlist) and the hook may add further material to be typeset. After it, `\clearpage` is called to ensure that all such material gets typeset. If there is nothing waiting the `\clearpage` has no effect.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

**enddocument/afterlastpage** As the name indicates this hook should not receive code that generates material for further pages. It is the right place to do some final housekeeping and possibly write out some information to the `.aux` file (which is still open at this point to receive data, but since there will be no more pages you need to write to it using `\immediate\write`). It is also the correct place to set up any testing code to be run when the `.aux` file is re-read in the next step.

After this hook has been executed the `.aux` file is closed for writing and then read back in to do some tests (e.g., looking for missing references or duplicated labels, etc.).

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

**enddocument/afteraux** At this point, the `.aux` file has been reprocessed and so this is a possible place for final checks and display of information to the user. However, for the latter you might prefer the next hook, so that your information is displayed after the (possibly longish) list of files if that got requested via `\listfiles`.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

**enddocument/info** This hook is meant to receive code that write final information messages to the terminal. It follows immediately after the previous hook (so both could have been combined, but then packages adding further code would always need to also supply an explicit rule to specify where it should go.

This hook already contains some code added by the kernel (under the labels `kernel/filelist` and `kernel/warnings`), namely the list of files when `\listfiles` has been used and the warnings for duplicate labels, missing references, font substitutions etc.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).

**enddocument/end** Finally, this hook is executed just in front of the final call to `\@@end`.

This is a one-time hook, so after it is executed, all further attempts to add code to it will execute such code immediately (see section 2.5).is it even possible to add code after this one?

There is also the hook `shipout/lastpage`. This hook is executed as part of the last `\shipout` in the document to allow package to add final `\special`'s to that page. Where this hook is executed in relation to those from the above list can vary from document to document. Furthermore to determine correctly which of the `\shipouts` is the last one,

L<sup>A</sup>T<sub>E</sub>X needs to be run several times, so initially it might get executed on the wrong page. See section 3.4 for where to find the details.

It is also possible to use the generic `env/document/end` hook which is executed by `\end`, i.e., just in front of the first hook above. Note however that the other generic `\end` environment hook, i.e., `env/document/after` will never get executed, because by that time L<sup>A</sup>T<sub>E</sub>X has finished the document processing.

### 3.4 Hooks provided by `\shipout` operations

There are several hooks and mechanisms added to L<sup>A</sup>T<sub>E</sub>X's process of generating pages. These are documented in `ltshipout-doc.pdf` or with code in `ltshipout-code.pdf`.

### 3.5 Hooks provided for paragraphs

The paragraph processing has been augmented to include a number of internal and public hooks. These are documented in `ltpara-doc.pdf` or with code in `ltpara-code.pdf`.

### 3.6 Hooks provided in NFSS commands

In languages that need to support for more than one script in parallel (and thus several sets of fonts, e.g., supporting both Latin and Japanese fonts), NFSS font commands such as `\sffamily` need to switch both the Latin family to “Sans Serif” and in addition alter a second set of fonts.

To support this, several NFSS commands have hooks to which such support can be added.

**rmfamily** After `\rmfamily` has done its initial checks and prepared a font series update, this hook is executed before `\selectfont`.

**sffamily** This is like the `rmfamily` hook, but for the `\sffamily` command.

**ttfamily** This is like the `rmfamily` hook, but for the `\ttfamily` command.

**normalfont** The `\normalfont` command resets the font encoding, family, series and shape to their document defaults. It then executes this hook and finally calls `\selectfont`.

**expand@font@defaults** The internal `\expand@font@defaults` command expands and saves the current defaults for the metafamilies (`rm/sf/tt`) and the metaseries (`bf/md`). If the NFSS machinery has been augmented, e.g., for Chinese or Japanese fonts, then further defaults may need to be set at this point. This can be done in this hook which is executed at the end of this macro.

**bfseries/defaults, bfseries** If the `\bfdefault` was explicitly changed by the user, its new value is used to set the `bf` series defaults for the metafamilies (`rm/sf/tt`) when `\bfseries` is called. The `bfseries/defaults` hook allows further adjustments to be made in this case. This hook is only executed if such a change is detected. In contrast, the `bfseries` hook is always executed just before `\selectfont` is called to change to the new series.

**mdseries/defaults, mdseries** These two hooks are like the previous ones but they are in the `\mdseries` command.

**selectfont** This hook is executed inside `\selectfont`, after the current values for *encoding*, *family*, *series*, *shape*, and *size* are evaluated and the new font is selected (and if necessary loaded). After the hook has executed, NFSS will still do any updates necessary for a new *size* (such as changing the size of `\strut`) and any updates necessary to a change in *encoding*.

This hook is intended for use cases where, in parallel to a change in the main font, some other fonts need to be altered (e.g., in CJK processing where you may need to deal with several different alphabets).

### 3.7 Hook provided by the mark mechanism

See `ltmarks-doc.pdf` for details.

**insertmark** This hook allows for a special setup while `\InsertMark` inserts a mark. It is executed in group so local changes only apply to the mark being inserted.

## 4 The Implementation

```

1 <@@=hook>
2 <*2ekernel | latexrelease>
3 \ExplSyntaxOn
4 <latexrelease> \NewModuleRelease{2020/10/01}{lthooks}
5 <latexrelease> {The~hook~management~system}
```

### 4.1 Debugging

```

\g__hook_debug_bool Holds the current debugging state.
6 \bool_new:N \g__hook_debug_bool
(End of definition for \g__hook_debug_bool.)

\hook_debug_on: Turns debugging on and off by redefining \__hook_debug:n.
\hook_debug_off:
\__hook_debug:n
\__hook_debug_gset:
7 \cs_new_eq:NN \__hook_debug:n \use_none:n
8 \cs_new_protected:Npn \hook_debug_on:
9 {
10   \bool_gset_true:N \g__hook_debug_bool
11   \__hook_debug_gset:
12 }
13 \cs_new_protected:Npn \hook_debug_off:
14 {
15   \bool_gset_false:N \g__hook_debug_bool
16   \__hook_debug_gset:
17 }
18 \cs_new_protected:Npn \__hook_debug_gset:
19 {
20   \cs_gset_protected:Npx \__hook_debug:n ##1
21   { \bool_if:NT \g__hook_debug_bool {##1} }
22 }
```

(End of definition for `\hook_debug_on:` and others. These functions are documented on page 216.)

## 4.2 Borrowing from internals of other kernel modules

`\__hook_str_compare:nn` Private copy of `\__str_if_eq:nn`  
`23 \cs_new_eq:NN \__hook_str_compare:nn \__str_if_eq:nn`  
*(End of definition for \\_\_hook\_str\_compare:nn.)*

## 4.3 Declarations

`\l__hook_tmpa_bool` Scratch boolean used throughout the package.  
`24 \bool_new:N \l__hook_tmpa_bool`  
*(End of definition for \l\_\_hook\_tmpa\_bool.)*

`\l__hook_return_tl` Scratch variables used throughout the package.  
`\l__hook_tmpa_tl` `25 \tl_new:N \l__hook_return_tl`  
`\l__hook_tmpb_tl` `26 \tl_new:N \l__hook_tmpa_tl`  
`27 \tl_new:N \l__hook_tmpb_tl`  
*(End of definition for \l\_\_hook\_return\_tl, \l\_\_hook\_tmpa\_tl, and \l\_\_hook\_tmpb\_tl.)*

`\g__hook_all_seq` In a few places we need a list of all hook names ever defined so we keep track if them in this sequence.  
`28 \seq_new:N \g__hook_all_seq`  
*(End of definition for \g\_\_hook\_all\_seq.)*

`\l__hook_cur_hook_tl` Stores the name of the hook currently being sorted.  
`29 \tl_new:N \l__hook_cur_hook_tl`  
*(End of definition for \l\_\_hook\_cur\_hook\_tl.)*

`\l__hook_work_prop` A property list holding a copy of the `\g__hook_⟨hook⟩_code_prop` of the hook being sorted to work on, so that changes don't act destructively on the hook data structure.  
`30 \prop_new:N \l__hook_work_prop`  
*(End of definition for \l\_\_hook\_work\_prop.)*

`\g__hook_used_prop` All hooks that receive code (for use in debugging display).  
`31 \prop_new:N \g__hook_used_prop`  
*(End of definition for \g\_\_hook\_used\_prop.)*

`\g__hook_hook_curr_name_tl` Default label used for hook commands, and a stack to keep track of packages within packages.  
`\g__hook_name_stack_seq` `32 \tl_new:N \g__hook_hook_curr_name_tl`  
`33 \seq_new:N \g__hook_name_stack_seq`  
*(End of definition for \g\_\_hook\_hook\_curr\_name\_tl and \g\_\_hook\_name\_stack\_seq.)*

`\__hook_tmp:w` Temporary macro for generic usage.  
`34 \cs_new_eq:NN \__hook_tmp:w ?`  
*(End of definition for \\_\_hook\_tmp:w.)*

`\c__hook_empty_tl` An empty token list, and one containing nine parameters.

`\c__hook_nine_parameters_tl`

```

35 \tl_const:Nn \c__hook_empty_tl { }
36 \tl_const:Nn \c__hook_nine_parameters_tl { #1#2#3#4#5#6#7#8#9 }

```

(End of definition for `\c__hook_empty_tl` and `\c__hook_nine_parameters_tl`.)

`\tl_gremove_once:Nx` Some variants of `expl3` functions.

`\tl_show:x` *FMi: should probably be moved to `expl3`*

`\tl_log:x`

`\tl_set:Ne` 37 `\cs_generate_variant:Nn \tl_gremove_once:Nn { Nx }`

`\cs_replacement_spec:c` 38 `\cs_generate_variant:Nn \tl_show:n { x }`

`\prop_put:Nne` 39 `\cs_generate_variant:Nn \tl_log:n { x }`

`\str_count:e` 40 `\cs_generate_variant:Nn \tl_set:Nn { Ne }`

41 `\cs_generate_variant:Nn \cs_replacement_spec:N { c }`

42 `\cs_generate_variant:Nn \prop_put:Nnn { Nne }`

43 `\cs_generate_variant:Nn \str_count:n { e }`

(End of definition for `\tl_gremove_once:Nx` and others.)

`\s__hook_mark` Scan mark used for delimited arguments.

44 `\scan_new:N \s__hook_mark`

(End of definition for `\s__hook_mark`.)

`\__hook_use_none_delimit_by_s_mark:w` Removes tokens until the next `\s__hook_mark`.

`\__hook_use_i_delimit_by_s_mark:nw`

```

45 \cs_new:Npn \__hook_use_none_delimit_by_s_mark:w #1 \s__hook_mark { }
46 \cs_new:Npn \__hook_use_i_delimit_by_s_mark:nw #1 #2 \s__hook_mark {#1}

```

(End of definition for `\__hook_use_none_delimit_by_s_mark:w` and `\__hook_use_i_delimit_by_s_mark:nw`.)

`\__hook_tl_set:cn` Private copies of a few `expl3` functions. `l3debug` will only add debugging to the public names, not to these copies, so we don't have to use `\debug_suspend:` and `\debug_resume:` everywhere.

Functions like `\__hook_tl_set:Nn` have to be redefined, rather than copied because in `expl3` they use `\__kernel_tl_(g)set:Nx`, which is also patched by `l3debug`.

```

47 \cs_new_protected:Npn \__hook_tl_set:cn #1#2
48 { \cs_set_nopar:cpx {#1} { \__kernel_exp_not:w {#2} } }

```

(End of definition for `\__hook_tl_set:cn`.)

`\__hook_tl_gset:Nn` Same as above.

`\__hook_tl_gset:Nx` 49 `\cs_new_protected:Npn \__hook_tl_gset:Nn #1#2`

`\__hook_tl_gset:cn` 50 `{ \cs_gset_nopar:Npx #1 { \__kernel_exp_not:w {#2} } }`

`\__hook_tl_gset:co` 51 `\cs_new_protected:Npn \__hook_tl_gset:Nx #1#2`

`\__hook_tl_gset:cx` 52 `{ \cs_gset_nopar:Npx #1 {#2} }`

53 `\cs_generate_variant:Nn \__hook_tl_gset:Nn { c, co }`

54 `\cs_generate_variant:Nn \__hook_tl_gset:Nx { c }`

(End of definition for `\__hook_tl_gset:Nn`.)

`\__hook_tl_gput_right:Nn` Same as above.

`\__hook_tl_gput_right:Ne` 55 `\cs_new_protected:Npn \__hook_tl_gput_right:Nn #1#2`

`\__hook_tl_gput_right:cn` 56 `{ \__hook_tl_gset:Nx #1 { \__kernel_exp_not:w \exp_after:wN { #1 #2 } } }`

57 `\cs_generate_variant:Nn \__hook_tl_gput_right:Nn { Ne, cn }`

(End of definition for `\_hook\_tl\_gput\_right:Nn`.)

`\_hook\_tl\_gput\_left:Nn` Same as above.

```
58 \cs_new_protected:Npn \_hook\_tl\_gput\_left:Nn #1#2
59 {
60   \_hook\_tl\_gset:Nx #1
61   { \_kernel\_exp\_not:w {#2} \_kernel\_exp\_not:w \exp\_after:wN {#1} }
62 }
```

(End of definition for `\_hook\_tl\_gput\_left:Nn`.)

`\_hook\_tl\_gset\_eq:NN` Same as above.

```
63 \cs_new_eq:NN \_hook\_tl\_gset\_eq:NN \tl\_gset\_eq:NN
```

(End of definition for `\_hook\_tl\_gset\_eq:NN`.)

`\_hook\_tl\_gclear:N` Same as above.

```
\_hook\_tl\_gclear:c
64 \cs_new_protected:Npn \_hook\_tl\_gclear:N #1
65 { \_hook\_tl\_gset\_eq:NN #1 \c\_empty\_tl }
66 \cs_generate_variant:Nn \_hook\_tl\_gclear:N { c }
```

(End of definition for `\_hook\_tl\_gclear:N`.)

## 4.4 Providing new hooks

### 4.4.1 The data structures of a hook

`\g\_hook_⟨hook⟩_code_prop` Hooks have a name (called `⟨hook⟩` in the description below) and for each hook we have  
`\_hook_⟨hook⟩` to provide a number of data structures. These are

`\g\_hook_⟨hook⟩_reversed_tl` `\g\_hook_⟨hook⟩_code_prop` A property list holding the code for the hook in separate  
`\g\_hook_⟨hook⟩_declared_tl` chunks. The keys are by default the package names that add code to the hook, but  
`\g\_hook_⟨hook⟩_parameter_tl` it is possible for packages to define other keys.  
`\_hook\_next_⟨hook⟩`  
`\_hook\_toplevel_⟨hook⟩` `\g\_hook_⟨hook⟩_rule_⟨label1⟩|⟨label2⟩_tl` A token list holding the relation be-  
between `⟨label1⟩` and `⟨label2⟩` in the `⟨hook⟩`. The `⟨labels⟩` are lexically (reverse)  
sorted to ensure that two labels always point to the same token list. For global  
rules, the `⟨hook⟩` name is ??.

`\_hook_⟨hook⟩` The code that is actually executed when the hook is called in the doc-  
ument is stored in this token list. It is constructed from the code chunks applying  
the information. This token list is named like that so that in case of an error inside  
the hook, the reported token list in the error is shorter, and to make it simpler to  
normalize hook names in `\_hook\_make\_name:n`.

`\g\_hook_⟨hook⟩_reversed_tl` Some hooks are “reversed”. This token list stores a - for  
such hook so that it can be identified. The - character is used because `⟨reversed⟩1`  
is +1 for normal hooks and -1 for reversed ones.

`\g\_hook_⟨hook⟩_declared_tl` This token list serves as a marker for the hook being  
officially declared. Its existence is tested to raise an error in case another declaration  
is attempted.

`\c_hook_⟨hook⟩_parameter_tl` This token list stores the parameter text for a declared hook (its existence almost completely intersects the token list above), which is used for managing hooks with arguments.

`\__hook_toplevel_⟨hook⟩` This token list stores the code inserted in the hook from the user’s document, in the `top-level` label. This label is special, and doesn’t participate in sorting. Instead, all code is appended to it and executed after (or before, if the hook is reversed) the normal hook code, but before the `next` code chunk.

`\__hook_next_⟨hook⟩` Finally there is extra code (normally empty) that is used on the next invocation of the hook (and then deleted). This can be used to define some special behavior for a single occasion from within the document. This token list follows the same naming scheme than the main `\__hook_⟨hook⟩` token list. It is called `\__hook_next_⟨hook⟩` rather than `\__hook_next_⟨hook⟩` because otherwise a hook whose name is `next_⟨hook⟩` would clash with the next code-token list of the hook called `⟨hook⟩`.

#### 4.4.2 On the existence of hooks

A hook may be in different states of existence. Here we give an overview of the internal commands to set up hooks and explain how the different states are distinguished. The actual implementation then follows in subsequent sections.

One problem we have to solve is that we need to be able to add code to hooks (e.g., with `\AddToHook`) even if that code has not yet been declared. For example, one package needs to write into a hook of another package, but that package may not get loaded, or is loaded only later. Another problem is that most hooks, but not the generic hooks, require a declaration.

We therefore distinguish the following states for a hook, which are managed by four different tests: structure existence (`\__hook_if_structure_exist:nTF`), creation (`\__hook_if_usable:nTF`), declaration (`\__hook_if_declared:nTF`) and disabled or not (`\__hook_if_disabled:nTF`)

**not existing** Nothing is known about the hook so far. This state can be detected with `\__hook_if_structure_exist:nTF` (which uses the false branch).

In this state the hook can be declared, disabled, rules can be defined or code could be added to it, but it is not possible to use the hook (with `\UseHook`).

**basic data structure set up** A hook is in this state when its basic data structure has been set up (using `\__hook_init_structure:n`). The data structure setup happens automatically when commands such as `\AddToHook` are used and the hook is at that point in state “not existing”.

In this state the four tests give the following results:

```
\__hook_if_structure_exist:nTF returns true.
      \__hook_if_usable:nTF returns false.
      \__hook_if_declared:nTF returns false.
      \__hook_if_disabled:nTF returns false.
```

The allowed actions are the same as in the “not existing” state.

**declared** A hook is in this state it is not disabled and was explicitly declared (e.g., with `\NewHook`). In this case the four tests give the following results:

```

\__hook_if_structure_exist:nTF returns true.
    \__hook_if_usable:nTF returns true.
    \__hook_if_declared:nTF returns true.
    \__hook_if_disabled:nTF returns false.

```

**usable** A hook is in this state if it is not disabled, was not explicitly declared but nevertheless is allowed to be used (with `\UseHook` or `\hook_use:n`). This state is only possible for generic hooks as they do not need to be declared. Therefore such hooks move directly from state “not existing” to “usable” the moment a declaration such as `\AddToHook` wants to add to the hook data structure. In this state the tests give the following results:

```

\__hook_if_structure_exist:nTF returns true.
    \__hook_if_usable:nTF returns true.
    \__hook_if_declared:nTF returns false.
    \__hook_if_disabled:nTF returns false.

```

**disabled** A generic hook in any state is moved to this state when `\DisableGenericHook` is used. This changes the tests to give the following results:

```

\__hook_if_structure_exist:nTF unchanged.
    \__hook_if_usable:nTF returns false.
    \__hook_if_declared:nTF returns true.
    \__hook_if_disabled:nTF returns true.

```

The structure test is unchanged (if the hook was unknown before it is **false**, otherwise **true**). The usable test returns **false** so that any `\UseHook` will bypass the hook from now on. The declared test returns **true** so that any further `\NewHook` generates an error and the disabled test returns **true** so that `\AddToHook` can return an error.

*FMi: maybe it should do this only after begin document?*

#### 4.4.3 Setting hooks up

`\hook_new:n` The `\hook_new:n` declaration declares a new hook and expects the hook `<name>` as its argument, e.g., `begindocument`.

```

\hook_new_with_args:nn
\__hook_new:nn
67 <latexrelease> \IncludeInRelease{2023/06/01}{\hook_new_with_args:nn}
68 <latexrelease> {Hooks-with-args}
69 \cs_new_protected:Npn \hook_new:n #1
70 { \__hook_normalize_hook_args:Nn \__hook_new:nn {#1} { 0 } }
71 \cs_new_protected:Npn \hook_new_with_args:nn #1 #2
72 { \__hook_normalize_hook_args:Nn \__hook_new:nn {#1} {#2} }
73 \cs_new_protected:Npn \__hook_new:nn #1 #2
74 {

```

We check if the hook was already *explicitly* declared with `\hook_new:n`, and if it already exists we complain, otherwise set the “created” flag for the hook so that it errors next time `\hook_new:n` is used.

```

75   \__hook_if_declared:nTF {#1}
76   { \msg_error:nnn { hooks } { exists } {#1} }
77   {
78     \tl_new:c { g__hook_#1_declared_tl }
79     \cs_undefine:c { __hook~#1 }
80     \cs_undefine:c { c__hook_#1_parameter_tl }
81     \__hook_make_usable:nn {#1} {#2}

```

In case there is already code in a hook, but it’s undeclared, run `\__hook_update_hook_code:n` to make it ready to be executed (see test `lthooks-034`).

```

82     \__hook_update_hook_code:n {#1}
83   }
84 }
85 <latexrelease>\EndIncludeInRelease
86 <latexrelease>\IncludeInRelease{2020/10/01}{\hook_new_with_args:nn}
87 <latexrelease>      {Hooks~with~args}
88 <latexrelease>\cs_gset_protected:Npn \hook_new:n #1
89 <latexrelease>  { \__hook_normalize_hook_args:Nn \__hook_new:n {#1} }
90 <latexrelease>\cs_undefine:N \__hook_new:nn
91 <latexrelease>\cs_gset_protected:Npn \__hook_new:n #1
92 <latexrelease>  {
93 <latexrelease>    \__hook_if_declared:nTF {#1}
94 <latexrelease>    { \msg_error:nnn { hooks } { exists } {#1} }
95 <latexrelease>    {
96 <latexrelease>      \tl_new:c { g__hook_#1_declared_tl }
97 <latexrelease>      \__hook_make_usable:n {#1}
98 <latexrelease>    }
99 <latexrelease>  }
100 <latexrelease>\cs_gset_protected:Npn \hook_new_with_args:nn #1 { }
101 <latexrelease>\EndIncludeInRelease

```

(End of definition for `\hook_new:n`, `\hook_new_with_args:nn`, and `\__hook_new:nn`. These functions are documented on page [213](#).)

`\__hook_make_usable:nn` This initializes all hook data structures for the hook but if used on its own doesn’t mark the hook as declared (as `\hook_new:n` does, so a later `\hook_new:n` on that hook will not result in an error. This command is internally used by `\hook_gput_code:nnn` when adding code to a generic hook.

```

102 <latexrelease>\IncludeInRelease{2023/06/01}{\__hook_make_usable:nn}
103 <latexrelease>      {Hooks~with~args}
104 \cs_new_protected:Npn \__hook_make_usable:nn #1 #2
105   {

```

Now we check if the hook’s data structure can be safely created without `expl3` raising errors, then we add the hook name to the list of all hooks and allocate the necessary data structures for the new hook, otherwise just do nothing.

```

106   \__hook_if_usable:nF {#1}
107   {
108     \seq_gput_right:Nn \g__hook_all_seq {#1}

```

Here we'll define the `\c__hook_⟨hook⟩_parameter_tl` to hold a run of parameters up to the number of arguments of the hook (`#2`).

```

109     \__kernel_cs_parm_from_arg_count:nnF
110     { \tl_const:cn { c__hook_#1_parameter_tl } } {#2}
111     {
112         \msg_error:nnnn { hooks } { too-many-args } {#1} {#2}
113         \tl_const:cx { c__hook_#1_parameter_tl }
114         { \exp_not:V \c__hook_nine_parameters_tl }
115     }

```

After that, use `\__hook_normalise_cs_args:nn` to correct the number of parameters of the macros `\__hook_toplevel_⟨hook⟩` and `\__hook_next_⟨hook⟩`. We need to be able to add code with arguments to a hook without prior knowledge of the number of arguments of that hook, so `lthooks` assumes 9 until the hook is properly declared and the number of arguments is known. `\__hook_normalise_cs_args:nn` does the normalization by using the `\c__hook_⟨hook⟩_parameter_tl` defined just above.

```

116     \__hook_normalise_cs_args:nn { _toplevel } {#1}
117     \__hook_normalise_cs_args:nn { _next } {#1}

```

This is only used by the actual code of the current hook, so declare it normally:

```

118     \__hook_code_gset:nn {#1} { }

```

Now ensure that the base data structure for the hook exists:

```

119     \__hook_init_structure:n {#1}

```

The call to `\__hook_normalise_code_pool:n` will correct any improper reference to arguments that don't exist in the hook, raising a low-level `TeX` error and doubling the offending parameter tokens. It has to be done after `\__hook_init_structure:n` because it operates on `\g__hook_⟨hook⟩_code_prop`.

```

120     \__hook_normalise_code_pool:n {#1}

```

The `\g__hook_⟨hook⟩_labels_clist` holds the sorted list of labels (once it got sorted). This is used only for debugging. These are defined conditionally, in case `\__hook_make_usable:nn` is being used to redefine a hook.

```

121     \clist_if_exist:cF { g__hook_#1_labels_clist }
122     {
123         \clist_new:c { g__hook_#1_labels_clist }

```

Some hooks should reverse the default order of code chunks. To signal this we have a token list which is empty for normal hooks and contains a `-` for reversed hooks.

```

124         \tl_new:c { g__hook_#1_reversed_tl }
125     }

```

The above is all in L3 convention, but we also provide an interface to legacy `LATEX 2ε` hooks of the form `\@...hook`, e.g., `\@begindocumenthook`. There have been a few of them and they have been added to using `\g@addto@macro`. If there exists such a macro matching the name of the new hook, i.e., `\@⟨hook-name⟩hook` and it is not empty then we add its contents as a code chunk under the label `legacy`.

**Warning: this support will vanish in future releases!**

```

126     \__hook_include_legacy_code_chunk:n {#1}
127     }
128 }
129 <latexrelease>\EndIncludeInRelease

```

```

130 <latexrelease>\IncludeInRelease{2020/10/01}{\__hook_make_usable:nn}
131 <latexrelease>          {Hooks~with~args}
132 <latexrelease>\cs_undefine:N \__hook_make_usable:nn
133 <latexrelease>\cs_gset_protected:Npn \__hook_make_usable:n #1
134 <latexrelease> {
135 <latexrelease>   \tl_if_exist:cF { __hook~#1 }
136 <latexrelease>   {
137 <latexrelease>     \seq_gput_right:Nn \g__hook_all_seq {#1}
138 <latexrelease>     \tl_new:c { __hook~#1 }
139 <latexrelease>     \__hook_init_structure:n {#1}
140 <latexrelease>     \clist_new:c { g__hook_#1_labels_clist }
141 <latexrelease>     \tl_new:c { g__hook_#1_reversed_tl }
142 <latexrelease>     \__hook_include_legacy_code_chunk:n {#1}
143 <latexrelease>   }
144 <latexrelease> }
145 <latexrelease>\EndIncludeInRelease

```

(End of definition for \\_\_hook\_make\_usable:nn.)

\\_\_hook\_init\_structure:n

This function declares the basic data structures for a hook without explicit declaring the hook itself. This is needed to allow adding to undeclared hooks. Here it is unnecessary to check whether all variables exist, since all three are declared at the same time (either all of them exist, or none).

It creates the hook code pool (\g\_\_hook\_<hook>\_code\_prop) and the top-level and next token lists. A hook is initialized with \\_\_hook\_init\_structure:n the first time anything is added to it. Initializing a hook just with \\_\_hook\_init\_structure:n will not make it usable with \hook\_use:n.

```

146 <latexrelease>\IncludeInRelease{2023/06/01}{\__hook_init_structure:n}
147 <latexrelease>          {Hooks~with~args}
148 <latexrelease>\cs_new_protected:Npn \__hook_init_structure:n #1
149 <latexrelease> {
150 <latexrelease>   \__hook_if_structure_exist:nF {#1}
151 <latexrelease>   {
152 <latexrelease>     \prop_new:c { g__hook_#1_code_prop }
153 <latexrelease>     \__hook_toplevel_gset:nn {#1} { }
154 <latexrelease>     \__hook_next_gset:nn {#1} { }
155 <latexrelease>   }
156 <latexrelease> }
157 <latexrelease>\EndIncludeInRelease

```

```

158 <latexrelease>\IncludeInRelease{2020/10/01}{\__hook_init_structure:n}
159 <latexrelease>          {Hooks~with~args}
160 <latexrelease>\cs_gset_protected:Npn \__hook_init_structure:n #1
161 <latexrelease> {
162 <latexrelease>   \__hook_if_structure_exist:nF {#1}
163 <latexrelease>   {
164 <latexrelease>     \prop_new:c { g__hook_#1_code_prop }
165 <latexrelease>     \tl_new:c { __hook_toplevel~#1 }
166 <latexrelease>     \tl_new:c { __hook_next~#1 }
167 <latexrelease>   }
168 <latexrelease> }
169 <latexrelease>\EndIncludeInRelease

```

(End of definition for \\_\_hook\_init\_structure:n.)

`\hook_new_reversed:n` Declare a new hook. The default ordering of code chunks is reversed, signaled by setting the token list to a minus sign.

`\hook_new_reversed_with_args:nn`

`\_hook_new_reversed:nn`

```

170 <latexrelease> \IncludeInRelease{2023/06/01}{\hook_new_reversed_with_args:nn}
171 <latexrelease> {Hooks-with-args}
172 \cs_new_protected:Npn \hook_new_reversed:n #1
173 { \_hook_normalize_hook_args:Nn \_hook_new_reversed:nn {#1} { 0 } }
174 \cs_new_protected:Npn \hook_new_reversed_with_args:nn #1 #2
175 { \_hook_normalize_hook_args:Nn \_hook_new_reversed:nn {#1} {#2} }
176 \cs_new_protected:Npn \_hook_new_reversed:nn #1 #2
177 {

`\__hook_include_legacy_code_chunk:n` The L<sup>A</sup>T<sub>E</sub>X legacy concept for hooks uses with hooks the following naming scheme in the code: `\@...hook`.

If this macro is not empty we add it under the label `legacy` to the current hook and then empty it globally. This way packages or classes directly manipulating commands such as `\@begindocumenthook` still get their hook data added.

**Warning: this support will vanish in future releases!**

```

229 \<latexrelease>\IncludeInRelease{2023/06/01}{\__hook_include_legacy_code_chunk:n}
230 \<latexrelease>{Hooks~with~args}
231 \cs_new_protected:Npn \__hook_include_legacy_code_chunk:n #1
232 {

```

If the macro doesn't exist (which is the usual case) then nothing needs to be done.

```

233 \tl_if_exist:cT { @#1hook }
234 {

```

Of course if the legacy hook exists but is empty, there is no need to add anything under `legacy` the legacy label.

```

235 \tl_if_empty:cF { @#1hook }
236 {

```

Here we set `\__hook_replacing_args_false:` because no legacy code will reference hook arguments.

```

237 \__hook_replacing_args_false:
238 \use:e
239 {
240 \__hook_hook_gput_code_do:nnn {#1} { legacy }
241 { \exp_not:v { @#1hook } }
242 }
243 \__hook_replacing_args_reset:

```

Once added to the hook, we need to clear it otherwise it might get added again later if the hook data gets updated.

```

```

(End of definition for \\_\_hook\_include\_legacy\_code\_chunk:n.)

#### 4.4.4 Disabling and providing hooks

**\hook\_disable\_generic:n** Disables a hook by creating its `\g__hook_{hook}_declared_tl` so that the hook errors when used with `\hook_new:n`, then it undefines `\__hook_{hook}` so that it may not be executed.

`\__hook_disable:n`  
`\__hook_if_disabled_p:n`  
`\__hook_if_disabled:nTF`

This does not clear any code that may be already stored in the hook's structure, but doesn't allow adding more code. `\__hook_if_disabled:nTF` uses that specific combination to check if the hook is disabled.

```

264 <latexrelease> \IncludeInRelease{2021/06/01}{\hook_disable_generic:n}
265 <latexrelease> {Disable~hooks}

266 \cs_new_protected:Npn \hook_disable_generic:n #1

## 4.5 Parsing a label

`\__hook_parse_label_default:nN` This macro checks if a label was given (not `\c_novalue_tl`), and if so, tries to parse the label looking for a leading `.` to replace by `\__hook_currname_or_default:.` #2 is a boolean representing if #1 is a label name.

```

330 \cs_new:Npn \__hook_parse_label_default:nN #1#2
331 {
332   \tl_if_novalue:nTF {#1}
333     { \__hook_currname_or_default: }
334     { \tl_trim_spaces_apply:nN {#1} \__hook_parse_dot_label:nN #2 }
335 }
```

(End of definition for `\__hook_parse_label_default:nN`.)

`\__hook_parse_dot_label:nN` Start by checking if the label is empty, which raises an error, and uses the fallback value.  
`\__hook_parse_dot_label:w` If not, split the label at a `./`, if any, and check if no tokens are before the `./`, or if the  
`\__hook_parse_dot_label_cleanup:w` only character is a `..`. If these requirements are fulfilled, the leading `.` is replaced with  
`\__hook_parse_dot_label_aux:w` `\__hook_currname_or_default:.` Otherwise the label is returned unchanged. #2 is a boolean representing if #1 is a label name.

```

336 \cs_new:Npn \__hook_parse_dot_label:nN #1#2
337 {
338   \tl_if_empty:nTF {#1}
339     {
340       \bool_if:NTF #2
341         { \msg_expandable_error:nn { hooks } { empty-label } }
342         { \msg_expandable_error:nn { hooks } { empty-hook } }
343       \__hook_currname_or_default:
344     }
345     {
346       \str_if_eq:nnTF {#1} { . }
347         { \__hook_currname_or_default: }
348         { \__hook_parse_dot_label:w #1 ./ \s__hook_mark }
349     }
350 }
351 \cs_new:Npn \__hook_parse_dot_label:w #1 ./ #2 \s__hook_mark
352 {
353   \tl_if_empty:nTF {#1}
354     { \__hook_parse_dot_label_aux:w #2 \s__hook_mark }
355     {
356       \tl_if_empty:nTF {#2}
357         { \__hook_make_name:n {#1} }
358         { \__hook_parse_dot_label_cleanup:w #1 ./ #2 \s__hook_mark }
359     }
360 }
361 \cs_new:Npn \__hook_parse_dot_label_cleanup:w #1 ./ \s__hook_mark {#1}
362 \cs_new:Npn \__hook_parse_dot_label_aux:w #1 ./ \s__hook_mark
363   { \__hook_currname_or_default: / \__hook_make_name:n {#1} }
```

(End of definition for `\__hook_parse_dot_label:nN` and others.)

`\__hook_currname_or_default:` This uses `\g__hook_hook_curr_name_tl` if it is set, otherwise it tries `\@currname`. If neither is set, it raises an error and uses the fallback value `label-missing`.

```

364 \cs_new:Npn \__hook_currname_or_default:
365 {
366   \tl_if_empty:NTF \g__hook_hook_curr_name_tl
367   {
368     \tl_if_empty:NTF \@currname
369     {
370       \msg_expandable_error:nnn { latex2e } { should-not-happen }
371       { Empty~default~label. }
372       \__hook_make_name:n { label-missing }
373     }
374     { \@currname }
375   }
376   { \g__hook_hook_curr_name_tl }
377 }

```

(End of definition for `\__hook_currname_or_default:`.)

`\__hook_make_name:n` This provides a standard sanitization of a hook’s name. It uses `\cs:w` to build a control sequence out of the hook name, then uses `\cs_to_str:N` to get the string representation of that, without the escape character. `\cs:w`-based expansion is used instead of `e`-based because Unicode characters don’t behave well inside `\expanded`. The macro adds the `\_hook_` prefix to the hook name to reuse the hook’s code token list to build the csname and avoid leaving “public” control sequences defined (as `\relax`) in TeX’s memory.

`\__hook_make_name:w`

```

378 \cs_new:Npn \__hook_make_name:n #1
379 {
380   \exp_after:wN \exp_after:wN \exp_after:wN \__hook_make_name:w
381   \exp_after:wN \token_to_str:N \cs:w __hook~ #1 \cs_end:
382 }
383 \exp_last_unbraced:NNNno
384 \cs_new:Npn \__hook_make_name:w #1 \tl_to_str:n { __hook~ } { }

```

(End of definition for `\__hook_make_name:n` and `\__hook_make_name:w`.)

`\__hook_normalize_hook_args:Nn` This is the standard route for normalizing hook and label arguments. The main macro does the entire operation within a group so that csnames made by `\__hook_make_name:n` are wiped off before continuing. This means that this function cannot be used for `\hook_use:n!`

`\__hook_normalize_hook_args:Nnn`

`\__hook_normalize_hook_rule_args:Nnnnn`

`\__hook_normalize_hook_args_aux:Nn`

```

385 \cs_new_protected:Npn \__hook_normalize_hook_args_aux:Nn #1 #2
386 {
387   \group_begin:
388   \use:e
389   {
390     \group_end:
391     \exp_not:N #1 #2
392   }
393 }
394 \cs_new_protected:Npn \__hook_normalize_hook_args:Nn #1 #2
395 {
396   \__hook_normalize_hook_args_aux:Nn #1
397   { { \__hook_parse_label_default:nN {#2} \c_false_bool } }
398 }

```

```

399 \cs_new_protected:Npn \__hook_normalize_hook_args:Nnn #1 #2 #3
400 {
401   \__hook_normalize_hook_args_aux:Nn #1
402   {
403     { \__hook_parse_label_default:nN {#2} \c_false_bool }
404     { \__hook_parse_label_default:nN {#3} \c_true_bool }
405   }
406 }
407 \cs_new_protected:Npn \__hook_normalize_hook_rule_args:Nnnnn #1 #2 #3 #4 #5
408 {
409   \__hook_normalize_hook_args_aux:Nn #1
410   {
411     { \__hook_parse_label_default:nN {#2} \c_false_bool }
412     { \__hook_parse_label_default:nN {#3} \c_true_bool }
413     { \tl_trim_spaces:n {#4} }
414     { \__hook_parse_label_default:nN {#5} \c_true_bool }
415   }
416 }

```

(End of definition for \\_\_hook\_normalize\_hook\_args:Nn and others.)

\\_\_hook\_curr\_name\_push:n The token list \g\_\_hook\_hook\_curr\_name\_tl stores the name of the current package/file to be used as the default label in hooks. Providing a consistent interface is tricky because packages can be loaded within packages, and some packages may not use \SetDefaultHookLabel to change the default label (in which case \@currname is used).

To pull that one off, we keep a stack that contains the default label for each level of input. The bottom of the stack contains the default label for the top-level (this stack should never go empty). If we're building the format, set the default label to be top-level:

```

417 \tl_gset:Nn \g__hook_hook_curr_name_tl { top-level }

```

Then, in case we're in latexrelease we push something on the stack to support roll forward. But in some rare cases, latexrelease may be loaded inside another package (notably platexrelease), so we'll first push the top-level entry:

```

418 <latexrelease> \seq_if_empty:NT \g__hook_name_stack_seq
419 <latexrelease> { \seq_gput_right:Nn \g__hook_name_stack_seq { top-level } }

```

then we dissect the \@currnamestack, adding \@currname to the stack:

```

420 <latexrelease> \cs_set_protected:Npn \__hook_tmp:w #1 #2 #3
421 <latexrelease> {
422   <latexrelease> \quark_if_recursion_tail_stop:n {#1}
423   <latexrelease> \seq_gput_right:Nn \g__hook_name_stack_seq {#1}
424   <latexrelease> \__hook_tmp:w
425   <latexrelease> }
426 <latexrelease> \exp_after:wN \__hook_tmp:w \@currnamestack
427 <latexrelease> \q_recursion_tail \q_recursion_tail
428 <latexrelease> \q_recursion_tail \q_recursion_stop

```

and finally set the default label to be the \@currname:

```

429 <latexrelease> \tl_gset:Nx \g__hook_hook_curr_name_tl { \@currname }
430 <latexrelease> \seq_gpop_right:NN \g__hook_name_stack_seq \l__hook_tmpa_tl

```

Two commands keep track of the stack: when a file is input, \\_\_hook\_curr\_name\_push:n pushes the current default label onto the stack and sets the new default label (all in one go):

```

431 \cs_new_protected:Npn \__hook_curr_name_push:n #1
432 { \exp_args:Nx \__hook_curr_name_push_aux:n { \__hook_make_name:n {#1} } }
433 \cs_new_protected:Npn \__hook_curr_name_push_aux:n #1
434 {
435   \tl_if_blank:nTF {#1}
436   { \msg_error:nn { hooks } { no-default-label } }
437   {
438     \str_if_eq:nnTF {#1} { top-level }
439     {
440       \msg_error:nnnnn { hooks } { set-top-level }
441       { to } { PushDefaultHookLabel } {#1}
442     }
443     {
444       \seq_gpush:NV \g__hook_name_stack_seq \g__hook_hook_curr_name_tl
445       \tl_gset:Nn \g__hook_hook_curr_name_tl {#1}
446     }
447   }
448 }

```

and when an input is over, the topmost item of the stack is popped, since that label will not be used again, and `\g__hook_hook_curr_name_tl` is updated to equal the now topmost item of the stack:

```

449 \cs_new_protected:Npn \__hook_curr_name_pop:
450 {
451   \seq_gpop:NNTF \g__hook_name_stack_seq \l__hook_return_tl
452   { \tl_gset_eq:NN \g__hook_hook_curr_name_tl \l__hook_return_tl }
453   { \msg_error:nn { hooks } { extra-pop-label } }
454 }

```

At the end of the document we want to check if there was no `\__hook_curr_name_push:n` without a matching `\__hook_curr_name_pop:` (not a critical error, but it might indicate that something else is not quite right):

```

455 \tl_gput_right:Nn \@kernel@after@enddocument@afterlastpage
456 { \__hook_end_document_label_check: }
457 \cs_new_protected:Npn \__hook_end_document_label_check:
458 {
459   \seq_gpop:NNT \g__hook_name_stack_seq \l__hook_return_tl
460   {
461     \msg_error:nnx { hooks } { missing-pop-label }
462     { \g__hook_hook_curr_name_tl }
463     \tl_gset_eq:NN \g__hook_hook_curr_name_tl \l__hook_return_tl
464     \__hook_end_document_label_check:
465   }
466 }

```

The token list `\g__hook_hook_curr_name_tl` is but a mirror of the top of the stack.

Now define a wrapper that replaces the top of the stack with the argument, and updates `\g__hook_hook_curr_name_tl` accordingly.

```

467 \cs_new_protected:Npn \__hook_set_default_hook_label:n #1
468 {
469   \seq_if_empty:NNTF \g__hook_name_stack_seq
470   {
471     \msg_error:nnnnn { hooks } { set-top-level }
472     { for } { SetDefaultHookLabel } {#1}

```

`\__hook_set_default_hook_label:n`

```

473     }
474     { \exp_args:Nx
475       \__hook_set_default_label:n { \__hook_make_name:n {#1} } }
476   }

485 }

```

(End of definition for `\__hook_curr_name_push:n` and others.)

## 4.6 Adding or removing hook code

With `\hook_gput_code:nnn{<hook>}{<label>}{<code>}` a chunk of `<code>` is added to an existing `<hook>` labeled with `<label>`.

```

\hook_gput_code:nnn
\hook_gput_code_with_args:nnn
\__hook_gput_code:nnn
\__hook_gput_code_store:nnn
\__hook_hook_gput_code_do:nnn
\__hook_prop_gput_labeled_cleanup:nnn
\__hook_prop_gput_labeled_do:Nnnn
\__hook_hash_check:nTF
\__hook_hash_check_aux:w
486 \<latexrelease>\IncludeInRelease{2023/06/01}{\hook_gput_code:nnn}
487 \<latexrelease>{Hooks-with-args}
488 \cs_new_protected:Npn \hook_gput_code:nnn #1 #2 #3
489 {
490   \__hook_replacing_args_false:
491   \__hook_normalize_hook_args:Nnn \__hook_gput_code:nnn {#1} {#2} {#3}
492   \__hook_replacing_args_reset:
493 }
494 \cs_new_protected:Npn \hook_gput_code_with_args:nnn #1 #2 #3
495 {
496   \__hook_replacing_args_true:
497   \__hook_normalize_hook_args:Nnn \__hook_gput_code:nnn {#1} {#2} {#3}
498   \__hook_replacing_args_reset:
499 }

```

If `\AddToHookWithArguments` was used, do some sanity checking, and if it's not possible to use arguments at this point, fall back to regular `\AddToHook` by using `\__hook_replacing_args_false:`.

```

500 \cs_new_protected:Npn \__hook_gput_code:nnn #1 #2 #3
501 {
502   \__hook_chk_args_allowed:nn {#1} { AddToHook }

```

Then check if the code should be executed immediately, rather than stored:

```

503   \__hook_if_execute_immediately:nTF {#1}
504   {

```

`\AddToHookWithArguments` can't be used on one-time hooks (that were already used).

```

505     \__hook_if_replacing_args:TF
506     {
507       \msg_error:nnnn { hooks } { one-time-args }
508       {#1} { AddToHook }
509     }
510     { }
511   \use:n
512 }

```

```

513     { \_hook_gput_code_store:nnn {#1} {#2} }
514         {#3}
515     }
516 \cs_new_protected:Npn \_hook_gput_code_store:nnn #1 #2 #3
517 {

```

Then check if the hook is usable.

```

518     \_hook_if_usable:nTF {#1}

```

If so we simply add (or append) the new code to the property list holding different chunks for the hook. At `\begin{document}` this is then sorted into a token list for fast execution.

```

519     {
520         \_hook_hook_gput_code_do:nnn {#1} {#2} {#3}

```

However, if there is an update within the document we need to alter this execution code which is done by `\_hook_update_hook_code:n`. In the preamble this does nothing.

```

521         \_hook_update_hook_code:n {#1}
522     }

```

If the hook is not usable, before giving up, check if it's not disabled and otherwise try to declare it as a generic hook, if its name matches one of the valid patterns.

```

523     {
524         \_hook_if_disabled:nTF {#1}
525         { \msg_error:nnn { hooks } { hook-disabled } {#1} }
526         { \_hook_try_declaring_generic_hook:nnn {#1} {#2} {#3} }
527     }
528 }

```

This macro will unconditionally add a chunk of code to the given hook.

```

529 \cs_new_protected:Npn \_hook_hook_gput_code_do:nnn #1 #2 #3
530 {

```

However, first some debugging info if debugging is enabled:

```

531     \_hook_debug:n{\iow_term:x{[lthooks]~ Add~ to~
532         \_hook_if_usable:nF {#1} { undeclared~ }
533         hook~ ' #1'~ ( #2) \on@line
534         ^^J [lthooks] \@spaces
535         <-- \tl_to_str:n{#3}} }

```

Then try to get the code chunk labeled #2 from the hook. If there's code already there, then append #3 to that, otherwise just put #3. If the current label is `top-level`, the code is added to a dedicated token list `\_hook_toplevel_<hook>` that goes at the end of the hook (or at the beginning, for a reversed hook), just before `\_hook_next_<hook>`.

```

536     \str_if_eq:nnTF {#2} { top-level }
537     {
538         \str_if_eq:eeTF { top-level } { \_hook_currname_or_default: }
539     {

```

If the hook's basic structure does not exist, we need to declare it with `\_hook_init_structure:n`.

```

540         \_hook_init_structure:n {#1}

```

Then append to the `_toplevel` container for the hook.

```

541         \__hook_cs_gput_right:nnn { _toplevel } {#1} {#3}
542     }
543     { \msg_error:nnn { hooks } { misused-top-level } {#1} }
544 }
545 {

```

When adding to the code pool, we have to double hashes if `\AddToHook` was used (`replacing_args` is false), so that later it is turned into a single parameter token, rather than a parameter to the hook macro. We skip this step if there are no hashes at all in the argument: the token-by-token approach otherwise becomes a major performance issue when the contents of the hook are long.

```

546     \exp_args:Nx \__hook_prop_gput_labeled_cleanup:nnn
547     {
548         \__hook_if_replacing_args:TF

`\__hook_chk_args_allowed:nn` This macro checks if it is possible to add code with references to a hook's arguments for hook #1. It only does something if the function being run is `replacing_args`. This macro will error if the hook is declared and takes no arguments, then it will set `\__hook_replacing_args_false:` so that the macro which called it will add the code normally.

```

`\__hook_gput_undeclared_hook:nnn` Often it may happen that a package *A* defines a hook `foo`, but package *B*, that adds code to that hook, is loaded before *A*. In such case we need to add code to the hook before it is declared. An implicitly declared hook doesn't have arguments (in principle), so use `\c_false_bool` here.

```

668 \cs_new_protected:Npn \__hook_gput_undeclared_hook:nnn #1 #2 #3
669 {
670   \__hook_init_structure:n {#1}
671   \__hook_hook_gput_code_do:nnn {#1} {#2} {#3}
672 }

```

(End of definition for \\_\_hook\_gput\_undeclared\_hook:nnn.)

`\__hook_try_declaring_generic_hook:nnn`  
`\__hook_try_declaring_generic_next_hook:nn` These entry-level macros just pass the arguments along to the common `\__hook_try_declaring_generic_hook:nNNnn` with the right functions to execute when some action is to be taken.

The wrapper `\__hook_try_declaring_generic_hook:nnn` then defers `\hook_gput_code:nnn` if the generic hook was declared, or to `\__hook_gput_undeclared_hook:nnn` otherwise (the hook was tested for existence before, so at this point if it isn't generic, it doesn't exist).

The wrapper `\__hook_try_declaring_generic_next_hook:nn` for next-execution hooks does the same: it defers the code to `\hook_gput_next_code:nn` if the generic hook was declared, or to `\__hook_gput_next_do:nn` otherwise.

```

\\_\_hook\_try\_declaring\_generic\_hook:nNNnn now splits the hook name at the first /  
(if any) and first checks if it is a file-specific hook (they require some normalization) using  
\\_\_hook\_if\_file\_hook:wTF. If not then check it is one of a predefined set for generic  
names. We also split off the second component to see if we have to make a reversed hook.  
In either case the function returns <true> for a generic hook and <false> in other cases.

If the hook doesn't exist yet we check if it is a `cmd` hook and if so we attempt patching the command in addition to declaring the hook.

For some commands this will not be possible, in which case `\__hook_patch_cmd_-or_delay:Nnn` (defined in `ltxcmdhooks`) will generate an appropriate error message.

```

757         \str_if_eq:nnT {#1} { cmd }
758         {
759             \__hook_try_put_cmd_hook:n {#5}
760             \__hook_make_usable:nn {#5} { 9 }
761             \use_none:nnn
762         }

```

Declare the hook always even if it can't really be used (error message generated elsewhere).

Here we use `\__hook_make_usable:nn`, so that a `\hook_new:n` is still possible later. Generic hooks (except `cmd` hooks) take no arguments, so use zero as the second argument.

```

763         \__hook_make_usable:nn {#5} { 0 }
764     }
765     \__hook_if_generic_reversed:nT {#5}
766     { \tl_gset:cn { g__hook_#5_reversed_tl } { - } }
767     \prg_return_true:
768 }
769 {

```

Generic hooks are all named `<type>/<name>/<place>`, where `<type>` and `<place>` are predefined (`\c__hook_generic_<type>/./<place>_tl`), and `<name>` is the variable component. Older releases had some hooks with the `<name>` in the third part, so the code below supports that syntax for a while, with a warning.

The `\exp_after:wN ... \exp:w` trick is there to remove the conditional structure inserted by `\__hook_try_declaring_generic_hook:wnTF` and thus allow access to the tokens that follow it, as is needed to keep things going.

When the deprecation cycle ends, the lines below should all be replaced by `\prg_return_false:`.

```

770     \__hook_if_deprecated_generic:nTF {#5}
771     {
772         \__hook_deprecated_generic_warn:n {#5}
773         \exp_after:wN \__hook_declare_deprecated_generic:NNn

`\__hook_file_hook_normalize:n`

```

\__hook_strip_double_slash:n 916 <latexrelease> \IncludeInRelease{2021/11/15}{\__hook_file_hook_normalize:n}
\__hook_strip_double_slash:w 917 <latexrelease> {Standardize-generic-hook-names}
918 <latexrelease> \EndIncludeInRelease

```

When a file-specific hook is found, before being declared it is lightly normalized by `\__hook_file_hook_normalize:n`. The current implementation just replaces two consecutive slashes (`//`) by a single one, to cope with simple cases where the user did something like `\def\input@path{./mypath/}`, in which case a hook would have to be `\AddToHook{file}/./mypath//file.tex/after`.

```

919 <latexrelease> \IncludeInRelease{2020/10/01}{\__hook_file_hook_normalize:n}
920 <latexrelease> {Standardize-generic-hook-names}

923 <latexrelease> \cs_new:Npn \__hook_strip_double_slash:n #1
924 <latexrelease> { \__hook_strip_double_slash:w #1 // \s__hook_mark }

```

This function is always called after testing if the argument is a file hook with `\__hook_if_file_hook:wTF`, so we can assume it has three parts (it is either `file/.../before` or `file/.../after`), so we use `#1/#2/#3 //` instead of just `#1 //` to prevent losing a slash if the file name is empty.

```

925 <latexrelease>\cs_new:Npn \__hook_strip_double_slash:w #1/#2/#3//#4\s__hook_mark

This macro is used to append code to the `toplevel` and `next` token lists, treating them correctly depending on their number of arguments, and depending on whether the code being added should have parameter tokens understood as parameters, or doubled to be stored as parameter tokens.

```

1049 <latexrelease> \IncludeInRelease{2023/06/01}{\_hook_cs_gput_right:nnn}
1050 <latexrelease> {Hooks-with-args}

```

Check if the current hook is declared and takes no arguments. In this case, we short-circuit and use the simpler and much faster approach that doesn't require hash-doubling.

```

1051 \cs_new_protected:Npn \_hook_cs_gput_right:nnn #1 #2
1052 {
1053   \if:w T
1054     \_hook_if_declared:nF {#2} { F }
1055     \tl_if_empty:cF { c\_hook\_#2\_parameter\_tl } { F }
1056     T
1057     \exp_after:wN \_hook_cs_gput_right_fast:nnn
1058   \else:
1059     \exp_after:wN \_hook_cs_gput_right_slow:nnn
1060   \fi:
1061   {#1} {#2}
1062 }
1063 \cs_new_protected:Npn \_hook_cs_gput_right_fast:nnn #1 #2 #3
1064 { \cs_gset:cpx { \_hook#1~#2 }
1065   { \exp_not:v { \_hook#1~#2 } \exp_not:n {#3} } }
1066 \cs_new_protected:Npn \_hook_cs_gput_right_slow:nnn #1 #2 #3
1067 {

```

The auxiliary `\_hook_code_gset_auxi:eeen` just does the assignment at the end. Its first argument is the parameter text of the macro, which is chosen here depending if `\c\_hook\_hook\_parameter\_tl` exists, if the hook is declared, and if it's a generic hook.

```

1068   \cs_if_exist:cF { \_hook#1~#2 }
1069   { \_hook_code_gset_aux:nnn {#1} {#2} { } }
1070   \_hook_code_gset_auxi:eeen
1071   {
1072     \_hook_if_declared:nTF {#2}
1073     { \tl_use:c { c\_hook\_#2\_parameter\_tl } }
1074     {
1075       \_hook_if_generic:nTF {#2}

```

```

1076         { \__hook_generic_parameter:n {#2} }
1077         { \c__hook_nine_parameters_tl }
1078     }
1079 }

```

Here we take the existing code in the macro, expand it with as many arguments as it takes, then double the hashes so the code can be reused.

PhO: Maybe can be improved. The case of adding to an empty cs can be optimized by quickly checking \cs\_replacement\_spec.

```

1080 {
1081     \exp_args:NNo \exp_args:No \__hook_double_hashes:n
1082     {
1083         \cs:w __hook#1~#2 \exp_last_unbraced:Ne \cs_end:
1084         { \__hook_braced_cs_parameter:n { __hook#1~#2 } }
1085     }
1086 }

```

Now the new code: if we are replacing arguments, then hashes are left untouched, otherwise they are doubled.

```

1087 {
1088     \__hook_if_replacing_args:TF
1089     { \exp_not:n }
1090     { \__hook_double_hashes:n }
1091     {#3}
1092 }

```

And finally, the csname which we'll define with all the above.

```

1093 { __hook#1~#2 }
1094 }

```

And as promised, the auxiliary that does the definition.

```

1095 \cs_new_protected:Npn \__hook_code_gset_auxi:nnnn #1 #2 #3 #4
1096 { \cs_gset:cpn {#4} #1 { #2 #3 } }

1128 <latexrelease>\EndIncludeInRelease

```

(End of definition for \\_\_hook\_code\_gset:nn and others.)

\\_\_hook\_normalise\_cs\_args:nn This macro normalizes the parameters of the macros \\_\_hook<type>\\_hook to take the right number of arguments after a hook is declared. At this point we know \c\_\_hook\\_hook\\_parameter\\_tl exists, so use that to count the arguments and use that as <parameter text> for the newly (re)defined macro.

```

1129 <latexrelease>\IncludeInRelease{2023/06/01}{\__hook_normalise_cs_args:nn}
1130 <latexrelease>{Hooks-with-args}
1131 \cs_new_protected:Npn \__hook_normalise_cs_args:nn #1 #2

1141         { \__hook_braced_cs_parameter:n { __hook#1~#2 } }
1142       }
1143     }
1144     { }
1145     { __hook#1~#2 }
1146   }
1147 }
1148 <latexrelease>\EndIncludeInRelease
1149 <latexrelease>\IncludeInRelease{2020/10/01}{\__hook_normalise_cs_args:nn}
1150 <latexrelease>{Hooks-with-args}
1151 <latexrelease>\cs_undefine:N \__hook_normalise_cs_args:nn
1152 <latexrelease>\EndIncludeInRelease

```

(End of definition for \\_\_hook\_normalise\_cs\_args:nn.)

\\_\_hook\_normalise\_code\_pool:n This one's a bit of a hack. It takes a hook, and iterates over its code pool (\g\_\_hook\\_hook\\_code\\_prop), redefining each code label to use only valid arguments. This is used when, for example, a code is added referencing arguments #1 and #2, but the hook has only #1. In this example, every reference to #2 is changed to ##2. This is done because

otherwise T<sub>E</sub>X will throw a low-level error every time some change happens to the hook (code is added, a rule is set, etc), which can get quite repetitive for no good reason.

```

1153 <latexrelease>\IncludeInRelease{2023/06/01}{\__hook_normalise_code_pool:n}
1154 <latexrelease>{Hooks~with~args}
1155 \cs_new_protected:Npn \__hook_normalise_code_pool:n #1
1156 {

```

First, call `\__hook_set_normalise_fn:nn` with the hook name to set everything up, then we'll loop over the hook's code pool applying the normalization above. After that's done, copy the temporary property list back to the hook's.

```

1157   \__hook_set_normalise_fn:nn {#1} { Offending~label:~'##1' }
1158   \prop_clear:N \l__hook_work_prop
1159   \prop_map_function:cN { g__hook_#1_code_prop } \__hook_normalise_fn:nn
1160   \prop_gset_eq:cN { g__hook_#1_code_prop } \l__hook_work_prop
1161 }

```

The sole purpose of this function is to define `\__hook_normalise_fn:nn`, which will then do the correcting of the code being added to the hook.

```

1162 \cs_new_protected:Npn \__hook_set_normalise_fn:nn #1 #2
1163 {

```

To start, we define two auxiliary token lists. `\l__hook_tmpb_tl` contains:

```

    {\c__hook_hashes_tl 1}
    {\c__hook_hashes_tl 2}
    ...
    {\c__hook_hashes_tl 9}

1164   \cs_set:Npn \__hook_tmp:w ##1##2##3##4##5##6##7##8##9 { }
1165   \tl_set:Nx \l__hook_tmpb_tl
1166     { \__hook_braced_cs_parameter:n { __hook_tmp:w } }
1167   \group_begin:
1168     \__hook_tl_set:cn { c__hook_hash_tl } { \exp_not:N \c__hook_hashes_tl }
1169     \use:e
1170     {
1171   \group_end:
1172   \tl_set:Nn \exp_not:N \l__hook_tmpb_tl { \l__hook_tmpb_tl }
1173   }

```

And `\l__hook_tmpa_tl` contains:

```

    {\c__hook_hash_tl 1}
    {\c__hook_hash_tl 2}
    ...
    {\c__hook_hash_tl <n>}

```

with `<n>` being the number of arguments declared for the hook.

```

1174   \exp_last_unbraced:NNf
1175   \cs_set:Npn \__hook_tmp:w { \__hook_parameter:n {#1} } { }
1176   \tl_set:Nx \l__hook_tmpa_tl
1177     { \__hook_braced_cs_parameter:n { __hook_tmp:w } }

```

Now this function does the fun part. It is meant to be used with `\prop_map_function:NN`, taking a label name in `##1` and the code stored in that label in `##2`.

```

1178   \cs_gset_protected:Npx \__hook_normalise_fn:nn ##1 ##2
1179   {

```

Here we'll define two auxiliary macros: the first one throws an error when it detects an invalid argument reference. It piggybacks on T<sub>E</sub>X's low-level "Illegal parameter number" error, but it defines a weirdly-named control sequence so that the error comes out nicely formatted. For example, if the label "badpkg" adds some code that references argument #3 in the hook "foo", which takes only two arguments, the error will be:

```
! Illegal parameter number in definition of hook 'foo'.
(hooks)          Offending label: 'badpkg'.
<to be read again>
3
```

At the point of this definition, the error is raised if the code happens to reference an invalid argument. If it was possible to detect that this definition raised no error, the next step would be unnecessary. We'll do all this in a group so this weird definition doesn't leak out, and set `\tex_escapechar:D` to `-1` so this hack shows up extra nice in the case of an error.

```
1180 \group_begin:
1181 \int_set:Nn \tex_escapechar:D { -1 }
1182 \cs_set:cpn
1183 {
1184 hook~'#1'. ^^J
1185 (hooks) \prg_replicate:nn { 13 } { ~ }
1186 #2 % more message text
1187 }
1188 \exp_not:v { c__hook_#1_parameter_tl }
1189 {##2}
1190 \group_end:
```

This next macro, with a much less fabulous name, takes always nine arguments, and it just transfers the code `##2` under the label `##1` to the temporary property list. The first  $\langle n \rangle$  arguments are taken from `\l__hook_tmpa_tl`, and the other  $9 - \langle n \rangle$  taken from `\l__hook_tmpb_tl` (which contains twice as many # tokens as the former). Then, `\__hook_double_hashes:n` is used to double non-argument hashes, and expand the `\c__hook_hash_tl` and `\c__hook_hashes_tl` to the actual parameter tokens.

```
1191 \cs_set:Npn \exp_not:N \__hook_tmp:w
1192 \exp_not:V \c__hook_nine_parameters_tl
1193 {
1194 \prop_put:Nne \exp_not:N \l__hook_work_prop
1195 {##1} { \exp_not:N \__hook_double_hashes:n {##2} }
1196 }
```

This next macro, with a much less fabulous name, takes always nine arguments, and it just transfers the code `##2` under the label `##1` to the temporary property list. The first  $\langle n \rangle$  arguments are taken from `\l__hook_tmpa_tl`, and the other  $9 - \langle n \rangle$  taken from `\l__hook_tmpb_tl` (which contains twice as many # tokens as the former). Then, `\__hook_double_hashes:n` is used to double non-argument hashes, and expand the `\c__hook_hash_tl` and `\c__hook_hashes_tl` to the actual parameter tokens.

```
1197 \exp_not:N \__hook_tmp:w
1198 \exp_not:V \l__hook_tmpa_tl
1199 \exp_args:No \exp_not:o
1200 { \exp_after:wN \__hook_tmp:w \l__hook_tmpb_tl }
1201 }
1202 }
```

\__hook_braced_cs_parameter:n
\__hook_braced_hidden_loop:w
\__hook_cs_parameter_count:N
\__hook_cs_parameter_count:w
\__hook_cs_end:w

```

Looks at the *<parameter text>* of a control sequence, and returns a run of “hidden” braced parameters for that macro. This works as long as the macros take a simple run of zero to nine arguments. The parameters are “hidden” because the parameter tokens are returned inside \c\_\_hook\_hash\_tl instead of explicitly, so that \\_\_hook\_double\_hashes:n won’t touch these.

```

## 4.7 Setting rules for hooks code

`\g__hook_??_code_prop` Initially these variables simply used an empty “label” name (not two question marks).  
`\__hook~??` This was a bit unfortunate, because then `l3doc` complains about `__` in the middle of a  
`\g__hook_??_reversed_tl` command name when trying to typeset the documentation. However using a “normal”  
`\c__hook_??_parameter_tl` name such as `default` has the disadvantage of that being not really distinguishable from  
a real hook name. I now have settled for `??` which needs some gymnastics to get it into  
the csname, but since this is used a lot, the code should be fast, so this is not done with  
`c` expansion in the code later on.

`\__hook_` isn’t used, but it has to be defined to trick the code into thinking that  
`??` is actually a hook.

```

1309 \prop_new:c { g__hook_??_code_prop }
1310 \prop_new:c { __hook~?? }

```

Default rules are always given in normal ordering (never in reversed ordering). If  
such a rule is applied to a reversed hook it behaves as if the rule is reversed (e.g., **after**  
becomes **before**) because those rules are applied first and then the order is reversed.

```

1311 \tl_new:c { g__hook_??_reversed_tl }

```

The parameter text for the “default” hook is empty.

```

1312 <latexrelease>\IncludeInRelease{2023/06/01}{\c__hook_??_parameter_tl}
1313 <latexrelease>{Hooks-with-args}
1314 \tl_const:cn { c__hook_??_parameter_tl } { }
1315 <latexrelease>\EndIncludeInRelease
1316 <latexrelease>\IncludeInRelease{2020/10/01}{\c__hook_??_parameter_tl}
1317 <latexrelease>{Hooks-with-args}
1318 <latexrelease>\cs_undefine:c { c__hook_??_parameter_tl }
1319 <latexrelease>\EndIncludeInRelease

```

(End of definition for `\g_hook_??_code_prop` and others.)

`\hook_gset_rule:nnnn` With `\hook_gset_rule:nnnn{<hook>}{<label1>}{<relation>}{<label2>}` a relation is defined between the two code labels for the given `<hook>`. The special hook `??` stands for *any* hook, which sets a default rule (to be used if no other relation between the two hooks exist).

```

1320 \cs_new_protected:Npn \hook_gset_rule:nnnn #1#2#3#4
1321 {
1322   \__hook_normalize_hook_rule_args:Nnnnn \__hook_gset_rule:nnnn
1323   {#1} {#2} {#3} {#4}
1324 }
1325 <latexrelease>\IncludeInRelease{2022/06/01}{\__hook_gset_rule:nnnn}
1326 <latexrelease>      {Refuse-setting-rule-for-one-time-hooks}
1327 \cs_new_protected:Npn \__hook_gset_rule:nnnn #1#2#3#4
1328 {
1329   \__hook_if_deprecated_generic:nT {#1}
1330   {
1331     \__hook_deprecated_generic_warn:n {#1}
1332     \__hook_do_deprecated_generic:Nn \__hook_gset_rule:nnnn {#1}
1333     {#2} {#3} {#4}
1334     \__hook_use_none_delimit_by_s_mark:w
1335   }
1336   \__hook_if_execute_immediately:nT {#1}
1337   {

1376 <latexrelease>          {#1} {#2} {#3} {#4}
1377 <latexrelease>      }
1378 <latexrelease>      }
1379 <latexrelease> \EndIncludeInRelease

```

(End of definition for `\hook_gset_rule:nnnn` and `\_hook_gset_rule:nnnn`. This function is documented on page 215.)

`\_hook_rule_before_gset:nnn` Then we add the new rule. We need to normalize the rules here to allow for faster processing later. Given a pair of labels  $l_A$  and  $l_B$ , the rule  $l_A > l_B$  is the same as  $l_B < l_A$  only presented differently. But by normalizing the forms of the rule to a single representation, say,  $l_B < l_A$ , reduces the time spent looking for the rules later considerably.

Here we do that normalization by using `\(pdf)strcmp` to lexically sort labels  $l_A$  and  $l_B$  to a fixed order. This order is then enforced every time these two labels are used together.

Here we use `\_hook_label_pair:nn {<hook>} {<lA>} {<lB>}` to build a string  $l_B || l_A$  with a fixed order, and use `\_hook_label_ordered:nnTF` to apply the correct rule to the pair of labels, depending if it was sorted or not.

```

1380 \cs_new_protected:Npn \_hook_rule_before_gset:nnn #1#2#3
1381 {
1382   \_hook_tl_gset:cx
1383   { g__hook_#1_rule_ \_hook_label_pair:nn {#2} {#3} _tl }
1384   { \_hook_label_ordered:nnTF {#2} {#3} { < } { > } }
1385 }
1386 \cs_new_eq:cN { \_hook_rule_<_gset:nnn } \_hook_rule_before_gset:nnn
1387 \cs_new_protected:Npn \_hook_rule_after_gset:nnn #1#2#3
1388 {
1389   \_hook_tl_gset:cx
1390   { g__hook_#1_rule_ \_hook_label_pair:nn {#3} {#2} _tl }
1391   { \_hook_label_ordered:nnTF {#3} {#2} { < } { > } }
1392 }
1393 \cs_new_eq:cN { \_hook_rule_>_gset:nnn } \_hook_rule_after_gset:nnn

```

(End of definition for `\_hook_rule_before_gset:nnn` and others.)

`\_hook_rule_voids_gset:nnn` This rule removes (clears, actually) the code from label #3 if label #2 is in the hook #1.

```

1394 \cs_new_protected:Npn \_hook_rule_voids_gset:nnn #1#2#3
1395 {

```

```

1396 \__hook_tl_gset:cx
1397 { g__hook_#1_rule_ \__hook_label_pair:nn {#2} {#3} _tl }
1398 { \__hook_label_ordered:nnTF {#2} {#3} { -> } { <- } }
1399 }

```

(End of definition for \\_\_hook\_rule\_voids\_gset:nnn.)

These relations make an error/warning if labels #2 and #3 appear together in hook #1.

```

1400 \cs_new_protected:cpn { \__hook_rule_incompatible-error_gset:nnn } #1#2#3
1401 { \__hook_tl_gset:cn
1402   { g__hook_#1_rule_ \__hook_label_pair:nn {#2} {#3} _tl }
1403   { xE }
1404 }
1405 \cs_new_protected:cpn { \__hook_rule_incompatible-warning_gset:nnn } #1#2#3
1406 { \__hook_tl_gset:cn
1407   { g__hook_#1_rule_ \__hook_label_pair:nn {#2} {#3} _tl }
1408   { xW }
1409 }

```

(End of definition for \\_\_hook\_rule\_incompatible-error\_gset:nnn and  
\\_\_hook\_rule\_incompatible-warning\_gset:nnn.)

Undo a setting. \\_\_hook\_rule\_unrelated\_gset:nnn doesn't need to do anything, since we use \\_\_hook\_rule\_gclear:nnn before setting any rule.

```

1410 \cs_new_protected:Npn \__hook_rule_unrelated_gset:nnn #1#2#3 { }
1411 \cs_new_protected:Npn \__hook_rule_gclear:nnn #1#2#3
1412 { \cs_undefine:c { g__hook_#1_rule_ \__hook_label_pair:nn {#2} {#3} _tl } }

```

(End of definition for \\_\_hook\_rule\_unrelated\_gset:nnn and \\_\_hook\_rule\_gclear:nnn.)

Ensure that the lexically greater label comes first.

```

1413 \cs_new:Npn \__hook_label_pair:nn #1#2
1414 {
1415   \if_case:w \__hook_str_compare:nn {#1} {#2} \exp_stop_f:
1416     #1 | #1 % 0
1417   \or:   #1 | #2 % +1
1418   \else: #2 | #1 % -1
1419   \fi:
1420 }

```

(End of definition for \\_\_hook\_label\_pair:nn.)

Check that labels #1 and #2 are in the correct order (as returned by \\_\_hook\_label\_pair:nn) and if so return true, else return false.

```

1421 \prg_new_conditional:Npnn \__hook_label_ordered:nn #1#2 { TF }
1422 {
1423   \if_int_compare:w \__hook_str_compare:nn {#1} {#2} > 0 \exp_stop_f:
1424   \prg_return_true:
1425   \else:
1426   \prg_return_false:
1427   \fi:
1428 }

```

(End of definition for \\_\_hook\_label\_ordered:nnTF.)

`\__hook_if_label_case:nnnnn` To avoid doing the string comparison twice in `\__hook_initialize_single:NNn` (once with `\str_if_eq:nn` and again with `\__hook_label_ordered:nn`), we use a three-way branching macro that will compare #1 and #2 and expand to `\use_i:nnn` if they are equal, `\use_ii:nn` if #1 is lexically greater, and `\use_iii:nn` otherwise.

```

1429 \cs_new:Npn \__hook_if_label_case:nnnnn #1#2
1430 {
1431   \cs:w use_
1432   \if_case:w \__hook_str_compare:nn {#1} {#2}
1433     i \or: ii \else: iii \fi: :nnn
1434   \cs_end:
1435 }

```

(End of definition for `\__hook_if_label_case:nnnnn`.)

`\__hook_update_hook_code:n` Before `\begin{document}` this does nothing, in the body it reinitializes the hook code using the altered data.

```

1436 \cs_new_eq:NN \__hook_update_hook_code:n \use_none:n

```

(End of definition for `\__hook_update_hook_code:n`.)

`\__hook_initialize_all:` Initialize all known hooks (at `\begin{document}`), i.e., update the fast execution token lists to hold the necessary code in the right order.

```

1437 <latexrelease> \IncludeInRelease{2023/06/01}{\__hook_initialize_all:}
1438 <latexrelease> {Hooks-with-args}
1439 \cs_new_protected:Npn \__hook_initialize_all:
1440 {

```

First we change `\__hook_update_hook_code:n` which so far was a no-op to now initialize one hook. This way any later updates to the hook will run that code and also update the execution token list.

```

1441   \cs_gset_eq:NN \__hook_update_hook_code:n \__hook_initialize_hook_code:n

```

Now we loop over all hooks that have been defined and update each of them. Here we have to determine if the hook has arguments so that auxiliaries know what to do with hashes. We look at `\c__hook_<hook>_parameter_tl`, if it has any parameters, and set `replacing_args` accordingly.

```

1442   \__hook_debug:n { \prop_gclear:N \g__hook_used_prop }
1443   \seq_map_inline:Nn \g__hook_all_seq
1444   {
1445     \tl_if_empty:cTF { c__hook_##1_parameter_tl }
1446     { \__hook_replacing_args_false: }
1447     { \__hook_replacing_args_true: }
1448     \__hook_update_hook_code:n {##1}
1449     \__hook_replacing_args_reset:
1450   }

```

If we are debugging we show results hook by hook for all hooks that have data.

```

1451   \__hook_debug:n
1452   {
1453     \iow_term:x { ^^J[lthooks]~ All-initialized~(non-empty)~hooks: }
1454     \prop_map_inline:Nn \g__hook_used_prop
1455     {
1456       \iow_term:x
1457       { ^^J ~ ##1 ~ -> ~ \cs_replacement_spec:c { __hook-##1 } ~ }
1458     }
1459   }

```

After all hooks are initialized we change the “use” to just call the hook code and not initialize it (as this was already done in the preamble.

```

1460 \_\hook_post_initialization_defs:
1461 }

1462 <latexrelease>\EndIncludeInRelease

1489 <latexrelease>\EndIncludeInRelease

```

(End of definition for \\_\hook\_initialize\_all:.)

\\_\hook\_initialize\_hook\_code:n Initializing or reinitializing the fast execution hook code. In the preamble this is selectively done in case a hook gets used and at \begin{document} this is done for all hooks and afterwards only if the hook code changes.

```

1490 <latexrelease>\IncludeInRelease{2023/06/01}{\_\hook_initialize_hook_code:n}
1491 <latexrelease> {Hooks-with-args}
1492 \cs_new_protected:Npn \_\hook_initialize_hook_code:n #1
1493 {
1494 \_\hook_debug:n
1495 { \iow_term:x { ^^J[lthooks]~ Update-code-for-hook~'##1' \on@line :^^J } }

```

This does the sorting and the updates. First thing we do is to check if a legacy hook macro exists and if so we add it to the hook under the label `legacy`. This might make the hook non-empty so we have to do this before the then following test.

```

1496 \_\hook_include_legacy_code_chunk:n {##1}

```

If there aren't any code chunks for the current hook, there is no point in even starting the sorting routine so we make a quick test for that and in that case just update \\_\hook\_⟨hook⟩ to hold the top-level and next code chunks. If there are code chunks we call \\_\hook\_initialize\_single:NNn and pass to it ready made csnames as they are

needed several times inside. This way we save a bit on processing time if we do that up front.

```

1497   \__hook_if_usable:nT {#1}
1498   {
1499       \prop_if_empty:cTF { g__hook_#1_code_prop }
1500       {
1501           \__hook_code_gset:ne {#1}
1502           {

```

The hook may take arguments, so we add a run of braced parameters after the `_next` and `_toplevel` macros, so that the arguments passed to the hook are forwarded to them.

```

1503           \exp_not:c { __hook_toplevel~#1 }
1504           \__hook_braced_parameter:n {#1}
1505           \exp_not:c { __hook_next~#1 }
1506           \__hook_braced_parameter:n {#1}
1507       }
1508   }
1509   {

```

By default the algorithm sorts the code chunks and then saves the result in a token list for fast execution; this is done by adding the code chunks one after another, using `\tl_gput_right:NV`. When we sort code for a reversed hook, all we have to do is to add the code chunks in the opposite order into the token list. So all we have to do in preparation is to change two definitions that are used later on.

```

1510   \__hook_if_reversed:nTF {#1}
1511   { \cs_set_eq:NN \__hook_tl_gput:Nn \__hook_tl_gput_left:Nn
1512     \cs_set_eq:NN \__hook_clist_gput:NV \clist_gput_left:NV }
1513   { \cs_set_eq:NN \__hook_tl_gput:Nn \__hook_tl_gput_right:Nn
1514     \cs_set_eq:NN \__hook_clist_gput:NV \clist_gput_right:NV }

```

When sorting, some relations (namely voids) need to act destructively on the code property lists to remove code that shouldn't appear in the sorted hook token list, so we make a copy of the code property list that we can safely work on without changing the main one.

```

1515   \prop_set_eq:Nc \l__hook_work_prop { g__hook_#1_code_prop }
1516   \__hook_initialize_single:ccn
1517   { __hook~#1 } { g__hook_#1_labels_clist } {#1}

```

For debug display we want to keep track of those hooks that actually got code added to them, so we record that in `plist`. We use a `plist` to ensure that we record each hook name only once, i.e., we are only interested in storing the keys and the value is arbitrary.

```

1518   \__hook_debug:n

1564 \cs_new:Npn \__hook_seq_csname:n #1 { l__hook_label_#1_seq }

```

(End of definition for \\_\_hook\_tl\_csname:n and \\_\_hook\_seq\_csname:n.)

\l\_\_hook\_labels\_seq For the sorting I am basically implementing Knuth's algorithm for topological sorting as  
\l\_\_hook\_labels\_int given in TAOCP volume 1 pages 263–266. For this algorithm we need a number of local  
\l\_\_hook\_front\_tl variables:

- List of labels used in the current hook to label code chunks:

```

1565 \seq_new:N \l__hook_labels_seq

```

- Number of labels used in the current hook. In Knuth's algorithm this is called  $N$ :

```

1566 \int_new:N \l__hook_labels_int

```

- The sorted code list to be build is managed using two pointers one to the front of the queue and one to the rear. We model this using token list pointers. Knuth calls them  $F$  and  $R$ :

```
1567 \tl_new:N \l__hook_front_tl
1568 \tl_new:N \l__hook_rear_tl
```

- The data for the start of the queue is kept in this token list, it corresponds to what Don calls `QLINK[0]` but since we aren't manipulating individual words in memory it is slightly differently done:

```
1569 \tl_new:c { \__hook_tl_csname:n { 0 } }
```

(End of definition for `\l__hook_labels_seq` and others.)

`\__hook_initialize_single:NNn` implements the sorting of the code chunks for a hook and saves the result in the token list for fast execution (#4). The arguments are `<hook-code-plist>`, `<hook-code-tl>`, `<hook-top-level-code-tl>`, `<hook-next-code-tl>`, `<hook-ordered-labels-clist>` and `<hook-name>` (the latter is only used for debugging—the `<hook-rule-plist>` is accessed using the `<hook-name>`).

The additional complexity compared to Don's algorithm is that we do not use simple positive integers but have arbitrary alphanumeric labels. As usual Don's data structures are chosen in a way that one can omit a lot of tests and I have mimicked that as far as possible. The result is a restriction I do not test for at the moment: a label can't be equal to the number 0!

*FMi: Needs checking for, just in case ... maybe*

```
1570 <latexrelease> \IncludeInRelease{2023/06/01}{\__hook_initialize_single:NNn}
1571 <latexrelease> {Hooks-with-args}
1572 \cs_new_protected:Npn \__hook_initialize_single:NNn #1#2#3
1573 {
```

Step T1: Initialize the data structure ...

```
1574 \seq_clear:N \l__hook_labels_seq
1575 \int_zero:N \l__hook_labels_int
```

Store the name of the hook:

```
1576 \tl_set:Nn \l__hook_cur_hook_tl {#3}
```

We loop over the property list holding the code and record all the labels listed there. Only the rules for those labels are of interest to us. While we are at it we count them (which gives us the  $N$  in Knuth's algorithm). The prefix `label_` is added to the variables to ensure that labels named `front`, `rear`, `labels`, or `return` don't interact with our code.

```
1577 \prop_map_inline:Nn \l__hook_work_prop
1578 {
1579     \int_incr:N \l__hook_labels_int
1580     \seq_put_right:Nn \l__hook_labels_seq {##1}
1581     \__hook_tl_set:cn { \__hook_tl_csname:n {##1} } { 0 }
1582     \seq_clear_new:c { \__hook_seq_csname:n {##1} }
1583 }
```

Steps T2 and T3: Here we sort the relevant rules into the data structure...

This loop constitutes a square matrix of the labels in `\l__hook_work_prop` in the vertical and the horizontal directions. However, since the rule  $l_A\langle rel \rangle l_B$  is the same as  $l_B\langle rel \rangle^{-1}l_A$  we can cut the loop short at the diagonal of the matrix (*i.e.*, when both labels are equal), saving a good amount of time. The way the rules were set up (see the implementation of `\__hook_rule_before_gset:nnn` above) ensures that we have no rule in the ignored side of the matrix, and all rules are seen. The rules are applied in `\__hook_apply_label_pair:nnn`, which takes the properly-ordered pair of labels as argument.

```

1584 \prop_map_inline:Nn \l__hook_work_prop
1585 {
1586   \prop_map_inline:Nn \l__hook_work_prop
1587   {
1588     \__hook_if_label_case:nnnnn {##1} {####1}
1589     { \prop_map_break: }
1590     { \__hook_apply_label_pair:nnn {##1} {####1} }
1591     { \__hook_apply_label_pair:nnn {####1} {##1} }
1592     {#3}
1593   }
1594 }

```

Now take a breath, and look at the data structures that have been set up:

```

1595 \__hook_debug:n { \__hook_debug_label_data:N \l__hook_work_prop }

```

Step T4:

```

1596 \tl_set:Nn \l__hook_rear_tl { 0 }
1597 \tl_set:cn { \__hook_tl_csname:n { 0 } } { 0 }
1598 \seq_map_inline:Nn \l__hook_labels_seq
1599 {
1600   \int_compare:nNnT { \cs:w \__hook_tl_csname:n {##1} \cs_end: } = 0
1601   {
1602     \tl_set:cn { \__hook_tl_csname:n { \l__hook_rear_tl } } {##1}
1603     \tl_set:Nn \l__hook_rear_tl {##1}
1604   }
1605 }
1606 \tl_set_eq:Nc \l__hook_front_tl { \__hook_tl_csname:n { 0 } }
1607 \__hook_tl_gclear:N #1
1608 \clist_gclear:N #2

```

The whole loop gets combined in steps T5–T7:

```

1609 \bool_while_do:nn { ! \str_if_eq_p:Vn \l__hook_front_tl { 0 } }
1610 {

```

This part is step T5:

```

1611 \int_decr:N \l__hook_labels_int
1612 \prop_get:NVN \l__hook_work_prop \l__hook_front_tl \l__hook_return_tl
1613 \exp_args:NNV \__hook_tl_gput:Nn #1 \l__hook_return_tl

1614 \__hook_clist_gput:NV #2 \l__hook_front_tl
1615 \__hook_debug:n{ \iow_term:x{[lthooks]~ Handled~ code~ for~ \l__hook_front_tl} }

```

This is step T6, except that we don't use a pointer  $P$  to move through the successors, but instead use `##1` of the mapping function.

```

1616 \seq_map_inline:cn { \__hook_seq_csname:n { \l__hook_front_tl } }

```

```

1617 {
1618   \tl_set:cx { \__hook_tl_csname:n {##1} }
1619   { \int_eval:n
1620     { \cs:w \__hook_tl_csname:n {##1} \cs_end: - 1 }
1621   }
1622   \int_compare:nNnT
1623     { \cs:w \__hook_tl_csname:n {##1} \cs_end: } = 0
1624   {
1625     \tl_set:cn
1626       { \__hook_tl_csname:n { \l__hook_rear_tl } } {##1}
1627     \tl_set:Nn \l__hook_rear_tl {##1}
1628   }
1629 }

```

and here is step T7:

```

1630   \tl_set_eq:Nc \l__hook_front_tl
1631   { \__hook_tl_csname:n { \l__hook_front_tl } }

```

This is step T8: If we haven't moved the code for all labels (i.e., if `\l__hook_labels_int` is still greater than zero) we have a loop and our partial order can't be flattened out.

```

1632 }
1633 \int_compare:nNnF \l__hook_labels_int = 0
1634 {
1635   \iow_term:x{=====}
1636   \iow_term:x{Error:~ label~ rules~ are~ incompatible:}

```

This is not really the information one needs in the error case but it will do for now  
...

*FMi: improve output on a rainy day*

```

1637   \__hook_debug_label_data:N \l__hook_work_prop
1638   \iow_term:x{=====}
1639 }

```

After we have added all hook code to #1, we finish it off by adding extra code for the **top-level** (#2) and for one time execution (#3). These should normally be empty. The **top-level** code is added with `\__hook_tl_gput:Nn` as that might change for a reversed hook (then **top-level** is the very first code chunk added). The **next** code is always added last (to the right). The hook may take arguments, so we add a run of braced parameters after the `_next` and `_toplevel` macros, so that the arguments passed to the hook are forwarded to them.

```

1640   \exp_args:NNe \__hook_tl_gput:Nn #1
1641   { \exp_not:c { \__hook_toplevel~#3 } \__hook_braced_parameter:n {#3} }
1642   \__hook_tl_gput_right:Ne #1
1643   { \exp_not:c { \__hook_next~#3 } \__hook_braced_parameter:n {#3} }
1644   \use:e
1645   {
1646     \cs_gset:cpn { \__hook~#3 } \use:c { c__hook_#3_parameter_tl }
1647     { \exp_not:V #1 }
1648   }
1649 }

1650 \cs_generate_variant:Nn \__hook_initialize_single:NNn { cc }
1651 \latexrelease\EndIncludeInRelease

\\_\_hook\_tl\_gput:Nn These append either on the right (normal hook) or on the left (reversed hook). This is  
 \\_\_hook\_clist\_gput:NV setup up in \\_\_hook\_initialize\_hook\_code:n, elsewhere their behavior is undefined.

```

1735 \cs_new:Npn \__hook_tl_gput:Nn    { \ERROR }
1736 \cs_new:Npn \__hook_clist_gput:NV { \ERROR }

```

(End of definition for \\_\_hook\_tl\_gput:Nn and \\_\_hook\_clist\_gput:NV.)

\\_\_hook\_apply\_label\_pair:nnn This is the payload of steps T2 and T3 executed in the loop described above. This macro  
 \\_\_hook\_label\_if\_exist\_apply:nnnF assumes #1 and #2 are ordered, which means that any rule pertaining the pair #1 and #2  
 is \g\_\_hook\_<hook>\_rule\_#1|#2\_tl, and not \g\_\_hook\_<hook>\_rule\_#2|#1\_tl. This  
 also saves a great deal of time since we only need to check the order of the labels once.

The arguments here are <label1>, <label2>, <hook>, and <hook-code-plist>. We  
 are about to apply the next rule and enter it into the data structure. \\_\_hook\_apply\_-  
 label\_pair:nnn will just call \\_\_hook\_label\_if\_exist\_apply:nnnF for the <hook>,  
 and if no rule is found, also try the <hook> name ?? denoting a default hook rule.

\\_\_hook\_label\_if\_exist\_apply:nnnF will check if the rule exists for the given  
 hook, and if so call \\_\_hook\_apply\_rule:nnn.

```

1737 \cs_new_protected:Npn \__hook_apply_label_pair:nnn #1#2#3
1738 {

```

Extra complication: as we use default rules and local hook specific rules we first have to check if there is a local rule and if that exist use it. Otherwise check if there is a default rule and use that.

```
1739 \__hook_label_if_exist_apply:nnnF {#1} {#2} {#3}
1740 {
```

If there is no hook-specific rule we check for a default one and use that if it exists.

```
1741 \__hook_label_if_exist_apply:nnnF {#1} {#2} { ?? } { }
1742 }
1743 }
```

```
1744 \cs_new_protected:Npn \__hook_label_if_exist_apply:nnnF #1#2#3
1745 {
1746 \if_cs_exist:w g__hook_ #3 _rule_ #1 | #2 _tl \cs_end:
```

What to do precisely depends on the type of rule we have encountered. If it is a **before** rule it will be handled by the algorithm but other types need to be managed differently. All this is done in `\__hook_apply_rule:nnnN`.

```
1747 \__hook_apply_rule:nnn {#1} {#2} {#3}
1748 \exp_after:wN \use_none:n
1749 \else:
1750 \use:nn
1751 \fi:
1752 }
```

(End of definition for `\__hook_apply_label_pair:nnn` and `\__hook_label_if_exist_apply:nnnF`.)

`\__hook_apply_rule:nnn` This is the code executed in steps T2 and T3 while looping through the matrix This is part of step T3. We are about to apply the next rule and enter it into the data structure. The arguments are  $\langle label1 \rangle$ ,  $\langle label2 \rangle$ ,  $\langle hook-name \rangle$ , and  $\langle hook-code-plist \rangle$ .

```
1753 \cs_new_protected:Npn \__hook_apply_rule:nnn #1#2#3
1754 {
1755 \cs:w __hook_apply_
1756 \cs:w g__hook_#3_reversed_tl \cs_end: rule_
1757 \cs:w g__hook_ #3 _rule_ #1 | #2 _tl \cs_end: :nnn \cs_end:
1758 {#1} {#2} {#3}
1759 }
```

(End of definition for `\__hook_apply_rule:nnn`.)

`\__hook_apply_rule_<:nnn` The most common cases are  $<$  and  $>$  so we handle that first. They are relations  $<$  and  $>$  in TAOCP, and they dictate sorting.

```
\__hook_apply_rule_>:nnn
1760 \cs_new_protected:cpn { __hook_apply_rule_<:nnn } #1#2#3
1761 {
1762 \__hook_debug:n { \__hook_msg_pair_found:nnn {#1} {#2} {#3} }
1763 \tl_set:cx { \__hook_tl_csname:n {#2} }
1764 { \int_eval:n{ \cs:w \__hook_tl_csname:n {#2} \cs_end: + 1 } }
1765 \seq_put_right:cn{ \__hook_seq_csname:n {#1} }{#2}
1766 }
1767 \cs_new_protected:cpn { __hook_apply_rule_>:nnn } #1#2#3
1768 {
1769 \__hook_debug:n { \__hook_msg_pair_found:nnn {#1} {#2} {#3} }
1770 \tl_set:cx { \__hook_tl_csname:n {#1} }
1771 { \int_eval:n{ \cs:w \__hook_tl_csname:n {#1} \cs_end: + 1 } }
1772 \seq_put_right:cn{ \__hook_seq_csname:n {#2} }{#1}
1773 }
```

(End of definition for `\__hook_apply_rule_<:nnn` and `\__hook_apply_rule_>:nnn`.)

`\__hook_apply_rule_xE:nnn` These relations make two labels incompatible within a hook. `xE` makes raises an error if the labels are found in the same hook, and `xW` makes it a warning.

```

\__hook_apply_rule_xW:nnn
1774 \cs_new_protected:cpn { __hook_apply_rule_xE:nnn } #1#2#3
1775 {
1776   \__hook_debug:n { \__hook_msg_pair_found:nnn {#1} {#2} {#3} }
1777   \msg_error:nnnnnn { hooks } { labels-incompatible }
1778   {#1} {#2} {#3} { 1 }
1779   \use:c { __hook_apply_rule_>:nnn } {#1} {#2} {#3}
1780   \use:c { __hook_apply_rule_<:nnn } {#1} {#2} {#3}
1781 }
1782 \cs_new_protected:cpn { __hook_apply_rule_xW:nnn } #1#2#3
1783 {
1784   \__hook_debug:n { \__hook_msg_pair_found:nnn {#1} {#2} {#3} }
1785   \msg_warning:nnnnnn { hooks } { labels-incompatible }
1786   {#1} {#2} {#3} { 0 }
1787 }

```

(End of definition for `\__hook_apply_rule_xE:nnn` and `\__hook_apply_rule_xW:nnn`.)

`\__hook_apply_rule_>:nnn` If we see `->` we have to drop code for label `#3` and carry on. We could do a little better and drop everything for that label since it doesn't matter where we put such empty code. However that would complicate the algorithm a lot with little gain.<sup>12</sup> So we still unnecessarily try to sort it in and depending on the rules that might result in a loop that is otherwise resolved. If that turns out to be a real issue, we can improve the code.

Here the code is removed from `\l__hook_cur_hook_tl` rather than `#3` because the latter may be `??`, and the default hook doesn't store any code. Removing it instead from `\l__hook_cur_hook_tl` makes the default rules `->` and `<-` work properly.

```

1788 \cs_new_protected:cpn { __hook_apply_rule_>:nnn } #1#2#3
1789 {
1790   \__hook_debug:n
1791   {

2095     \_hook_if_cmd_hook:nT {#1}
2096     { \use_i:nnn { ~ (unknown ~ ) } }
2097     \use:n { ~ (#2 ~ ) }

```

```

2098         argument \int_compare:nNtT {#2} > { 1 } { s } )
2099     }
2100 }

```

(End of definition for `\hook_show:n` and others. These functions are documented on page 216.)

`\__hook_list_rules:nn` This macro takes a `<hook>` and an `<inline function>` and loops through each pair of `<labels>` in the `<hook>`, and if there is a relation between this pair of `<labels>`, the `<inline function>` is executed with `#1 = <relation>`, `#2 = <label1>|<label2>`, and `#3 = <hook>` (the latter may be the argument `#1` to `\__hook_list_rules:nn`, or `??` if it is a default rule).

```

2101 \cs_new_protected:Npn \__hook_list_rules:nn #1 #2
2102 {
2103     \prop_if_exist:cT { g__hook_#1_code_prop }
2104     {
2105         \cs_set_protected:Npn \__hook_tmp:w ##1 ##2 ##3 {#2}
2106         \prop_map_inline:cn { g__hook_#1_code_prop }
2107         {
2108             \prop_map_inline:cn { g__hook_#1_code_prop }
2109             {
2110                 \__hook_if_label_case:nnnnn {##1} {####1}
2111                 { \prop_map_break: }
2112                 { \__hook_list_one_rule:nnn {##1} {####1} }
2113                 { \__hook_list_one_rule:nnn {####1} {##1} }
2114                 {#1}
2115             }
2116         }
2117     }
2118 }

```

These two are quite similar to `\__hook_apply_label_pair:nnn` and `\__hook_label_if_exist_apply:nnnF`, respectively, but rather than applying the rule, they pass it to the `<inline function>`.

```

2119 \cs_new_protected:Npn \__hook_list_one_rule:nnn #1#2#3
2120 {
2121     \__hook_list_if_rule_exists:nnnF {#1} {#2} {#3}
2122     { \__hook_list_if_rule_exists:nnnF {#1} {#2} { ?? } { } }
2123 }
2124 \cs_new_protected:Npn \__hook_list_if_rule_exists:nnnF #1#2#3
2125 {

```

(End of definition for \\_\_hook\_gput\_next\_code:nn.)

\\_\_hook\_gput\_next\_do:nn

Start by sanity-checking with \\_\_hook\_chk\_args\_allowed:nn. Then check if the “next code” token list is empty: if so we need to add a \tl\_gclear:c to clear it, so the code lasts for one usage only. The token list is cleared early so that nested usages don’t get lost. \tl\_gclear:c is used instead of \tl\_gclear:N in case the hook is used in an expansion-only context, so the token list doesn’t expand before \tl\_gclear:N: that would make an infinite loop. Also in case the main code token list is empty, the hook code has to be updated to add the next execution token list.

## 4.9 Using the hook

**\hook\_use:n** **\hook\_use:n** as defined here is used in the preamble, where hooks aren't initialized by default. **\\_\_hook\_use\_initialized:n** is also defined, which is the non-**\protected** version for use within the document. Their definition is identical, except for the **\\_\_hook\_preamble\_hook:n** (which wouldn't hurt in the expandable version, but it would be an unnecessary extra expansion).

**\\_\_hook\_use\_initialized:n** holds the expandable definition while in the preamble. **\\_\_hook\_preamble\_hook:n** initializes the hook in the preamble, and is redefined to **\use\_none:n** at **\begin{document}**.

Both versions do the same thing internally: they check that the hook exists as given, and if so they use it as quickly as possible.

At **\begin{document}**, all hooks are initialized, and any change in them causes an update, so **\hook\_use:n** can be made expandable. This one is better not protected so that it can expand into nothing if containing no code. Also important in case of generic hooks that we do not generate a **\relax** as a side effect of checking for a csname. In contrast to the T<sub>E</sub>X low-level **\csname ... \endcsname** construct **\tl\_if\_exist:c** is careful to avoid this.

\\_\_hook\_use:wn \\_\_hook\_use:wn does a quick check to test if the current hook is a file hook: those need a special treatment. If it is not, the hook does not exist. If it is, then \\_\_hook\_try\_file\_hook:n \\_\_hook\_try\_file\_hook:n is called, and checks that the current hook is a file-specific hook using \\_\_hook\_if\_file\_hook:wTF. If it's not, then it's a generic file/ hook and is used if it exist.

If it is a file-specific hook, it passes through the same normalization as during declaration, and then it is used if defined. \\_\_hook\_if\_usable\_use:n checks if the hook exist, and calls \\_\_hook\_preamble\_hook:n if so, then uses the hook.

\hook\_use\_once:n For hooks that can and should be used only once we have a special use command that further inhibits the hook from getting more code added to it. This has the effect that any further code added to the hook is executed immediately rather than stored in the hook.

The code needs some gymnastics to prevent space trimming from the hook name, since `\hook_use:n` and `\hook_use_once:n` are documented to not trim spaces.

When a hook has arguments, the call to `\__hook_use_initialized:n`, should be the very last thing to happen, otherwise the arguments grabbed will be wrong. So, to clean up after the hook we need to cheat a bit and sneak the cleanup code at the end of the hook, along with the next execution code.

\\_\_hook\_use\_once\_set:n \\_\_hook\_use\_once\_set:n is used before the actual hook code is executed so that any usage of \AddToHook inside the hook causes the code to execute immediately. Setting \g\_\_hook\_⟨hook⟩\_reversed\_tl to I prevents further code from being added to the hook. \\_\_hook\_use\_once\_clear:n then clears the hook so that any further call to \hook\_use:n or \hook\_use\_once:n will expand to nothing.

## 4.10 Querying a hook

Simpler data types, like token lists, have three possible states; they can exist and be empty, exist and be non-empty, and they may not exist, in which case emptiness doesn't apply (though `\tl_if_empty:N` returns false in this case).

Hooks are a bit more complicated: they have several other states as discussed in 4.4.2. A hook may exist or not, and either way it may or may not be empty (even a hook that doesn't exist may be non-empty) or may be disabled.

A hook is said to be empty when no code was added to it, either to its permanent code pool, or to its “next” token list. The hook doesn't need to be declared to have code added to its code pool (it may happen that a package *A* defines a hook `foo`, but it's loaded after package *B*, which adds some code to that hook. In this case it is important that the code added by package *B* is remembered until package *A* is loaded).

All other states can only be queried with internal tests as the different states are irrelevant for package code.

`\hook_if_empty_p:n` Test if a hook is empty (that is, no code was added to that hook). A  $\langle\text{hook}\rangle$  being empty means that all three of its `\g__hook_<hook>_code_prop`, its `\__hook_toplevel_<hook>` and its `\__hook_next_<hook>` are empty.

`\hook_if_empty:nTF`

```

2469 <latexrelease> \IncludeInRelease{2023/06/01}{\hook_if_empty:n}

2472 {
2473     \if:w
2474         T
2475         \prop_if_exist:cT { g__hook_#1_code_prop }
2476         { \prop_if_empty:cF { g__hook_#1_code_prop } { F } }
2477         \__hook_cs_if_empty:cF { __hook_toplevel~#1 } { F }
2478         \__hook_cs_if_empty:cF { __hook_next~#1 } { F }
2479         T
2480         \prg_return_true:
2481     \else:
2482         \prg_return_false:
2483     \fi:
2484 }
2485 <latexrelease> \EndIncludeInRelease
2486 <latexrelease> \IncludeInRelease{2020/10/01}{\hook_if_empty:n}
2487 <latexrelease> {Hooks-with-args}
2488 <latexrelease> \prg_new_conditional:Npnn \hook_if_empty:n #1 { p , T , F , TF }
2489 <latexrelease> {

```

```

2490 <latexrelease> \_hook_if_structure_exist:nTF {#1}
2491 <latexrelease> {
2492 <latexrelease> \bool_lazy_and:nnTF
2493 <latexrelease> { \prop_if_empty_p:c { g__hook_#1_code_prop } }
2494 <latexrelease> {
2495 <latexrelease> \bool_lazy_and_p:nn
2496 <latexrelease> { \tl_if_empty_p:c { __hook_toplevel~#1 } }
2497 <latexrelease> { \tl_if_empty_p:c { __hook_next~#1 } }
2498 <latexrelease> }
2499 <latexrelease> { \prg_return_true: }
2500 <latexrelease> { \prg_return_false: }
2501 <latexrelease> }
2502 <latexrelease> { \prg_return_true: }
2503 <latexrelease> }
2504 <latexrelease> \EndIncludeInRelease

```

(End of definition for `\hook_if_empty:nTF`. This function is documented on page 216.)

`\_hook_if_usable_p:n` A hook is usable if the token list that stores the sorted code for that hook, `\_hook_<hook>`, exists. The property list `g__hook_<hook>_code_prop` cannot be used here because often it is necessary to add code to a hook without knowing if such hook was already declared, or even if it will ever be (for example, in case the package that defines it isn't loaded).

```

2505 \prg_new_conditional:Npnn \_hook_if_usable:n #1 { p , T , F , TF }
2506 {
2507 \cs_if_exist:cTF { __hook~#1 }
2508 { \prg_return_true: }
2509 { \prg_return_false: }
2510 }

```

(End of definition for `\_hook_if_usable:nTF`.)

`\_hook_if_structure_exist_p:n` An internal check if the hook has already its basic internal structure set up with `\_hook_init_structure:n`. This means that the hook was already used somehow (a code chunk or rule was added to it), but it still wasn't declared with `\hook_new:n`.

```

2511 \prg_new_conditional:Npnn \_hook_if_structure_exist:n #1 { p , T , F , TF }
2512 {
2513 \prop_if_exist:cTF { g__hook_#1_code_prop }
2514 { \prg_return_true: }
2515 { \prg_return_false: }
2516 }

```

(End of definition for `\_hook_if_structure_exist:nTF`.)

`\_hook_if_declared_p:n` Internal test to check if the hook was officially declared with `\hook_new:n` or a variant.

```

2517 \prg_new_conditional:Npnn \_hook_if_declared:n #1 { p , T , F , TF }
2518 {
2519 \tl_if_exist:cTF { g__hook_#1_declared_tl }
2520 { \prg_return_true: }
2521 { \prg_return_false: }
2522 }

```

(End of definition for `\_hook_if_declared:nTF`.)

`\__hook_if_reversed_p:n` An internal conditional that checks if a hook is reversed.

`\__hook_if_reversed:nTF`

```

2523 \prg_new_conditional:Npnn \__hook_if_reversed:n #1 { p , T , F , TF }
2524 {
2525   \exp_after:wN \__hook_use_none_delimit_by_s_mark:w
2526   \if:w - \cs:w g__hook_#1_reversed_tl \cs_end:
2527     \s__hook_mark \prg_return_true:
2528   \else:
2529     \s__hook_mark \prg_return_false:
2530   \fi:
2531 }

```

*(End of definition for \\_\_hook\_if\_reversed:nTF.)*

`\__hook_if_generic_p:n` An internal conditional that checks if a name belongs to a generic hook. The deprecated version needs to check if #3 is empty to avoid returning true on file/before, for example.

`\__hook_if_generic:nTF`

`\__hook_if_deprecated_generic_p:n`

`\__hook_if_deprecated_generic:nTF`

```

2532 \prg_new_conditional:Npnn \__hook_if_generic:n #1 { T, TF }
2533 { \__hook_if_generic:w #1 / / / \s__hook_mark }
2534 \cs_new:Npn \__hook_if_generic:w #1 / #2 / #3 / #4 \s__hook_mark
2535 {
2536   \cs_if_exist:cTF { c__hook_generic_#1/./#3_tl }
2537   { \prg_return_true: }
2538   { \prg_return_false: }
2539 }
2540 \prg_new_conditional:Npnn \__hook_if_deprecated_generic:n #1 { T, TF }
2541 { \__hook_if_deprecated_generic:w #1 / / / \s__hook_mark }
2542 \cs_new:Npn \__hook_if_deprecated_generic:w #1 / #2 / #3 / #4 \s__hook_mark
2543 {
2544   \cs_if_exist:cTF { c__hook_deprecated_#1/./#2_tl }
2545   {

2787 <latexrelease> \def \DisableGenericHook #1 { }
2788 <latexrelease> \EndIncludeInRelease
```

**\AddToHook**

**\AddToHookWithArguments**

```
2789 <latexrelease> \IncludeInRelease{2023/06/01}{\AddToHookWithArguments}
2790 <latexrelease> {Hooks-with-args}
2791 \NewDocumentCommand \AddToHook { m o +m }
2792 { \hook_gput_code:nnn {#1} {#2} {#3} }
2793 \NewDocumentCommand \AddToHookWithArguments { m o +m }
2794 { \hook_gput_code_with_args:nnn {#1} {#2} {#3} }
2795 <latexrelease> \EndIncludeInRelease
2796 <latexrelease> \IncludeInRelease{2020/10/01}{\AddToHookWithArguments}
2797 <latexrelease> {Hooks-with-args}
2798 <latexrelease> \cs_new_protected:Npn \AddToHookWithArguments #1 #2 #3 { }
2799 <latexrelease> \EndIncludeInRelease
```

(End of definition for \AddToHook and \AddToHookWithArguments. These functions are documented on page 204.)

**\AddToHookNext**

**\AddToHookNextWithArguments**

```
2800 <latexrelease> \IncludeInRelease{2023/06/01}{\AddToHookNextWithArguments}
2801 <latexrelease> {Hooks-with-args}
2802 \NewDocumentCommand \AddToHookNext { m +m }
2803 { \hook_gput_next_code:nn {#1} {#2} }
2804 \NewDocumentCommand \AddToHookNextWithArguments { m +m }
2805 { \hook_gput_next_code_with_args:nn {#1} {#2} }
2806 <latexrelease> \EndIncludeInRelease
2807 <latexrelease> \IncludeInRelease{2020/10/01}{\AddToHookNextWithArguments}
2808 <latexrelease> {Hooks-with-args}
2809 <latexrelease> \cs_new_protected:Npn \AddToHookNextWithArguments #1 #2 { }
2810 <latexrelease> \EndIncludeInRelease
```

(End of definition for \AddToHookNext and \AddToHookNextWithArguments. These functions are documented on page 206.)

**\ClearHookNext**

```
2811 \NewDocumentCommand \ClearHookNext { m }
2812 { \hook_gclear_next_code:n {#1} }
```

(End of definition for \ClearHookNext. This function is documented on page 206.)

**\RemoveFromHook**

```
2813 \NewDocumentCommand \RemoveFromHook { m o }
2814 { \hook_gremove_code:nn {#1} {#2} }
```

(End of definition for \RemoveFromHook. This function is documented on page 205.)

**\SetDefaultHookLabel**

**\PushDefaultHookLabel**

**\PopDefaultHookLabel**

Now define a wrapper that replaces the top of the stack with the argument, and updates `\g__hook_hook_curr_name_tl` accordingly.

```
2815 \NewDocumentCommand \SetDefaultHookLabel { m }
2816 { \__hook_set_default_hook_label:n {#1} }
```

The label is only automatically updated with `\@onefilewithoptions` (`\usepackage` and `\documentclass`), but some packages, like `TikZ`, define package-like interfaces, like `\usetikzlibrary` that are wrappers around `\input`, so they inherit the default label currently in force (usually `top-level`, but it may change if loaded in another package). To provide a package-like behavior also for hooks in these files, we provide high-level access to the default label stack.

```

2817 \NewDocumentCommand \PushDefaultHookLabel { m }
2818 { \__hook_curr_name_push:n {#1} }
2819 \NewDocumentCommand \PopDefaultHookLabel { }
2820 { \__hook_curr_name_pop: }

```

The current label stack holds the labels for all files but the current one (more or less like `\@currnamestack`), and the current label token list, `\g__hook_hook_curr_name_tl`, holds the label for the current file. However `\@pushfilename` happens before `\@currname` is set, so we need to look ahead to get the `\@currname` for the label. `expl3` also requires the current file in `\@pushfilename`, so here we abuse `\@expl@push@filename@aux@@` to do `\__hook_curr_name_push:n`.

```

2821 \cs_gset_protected:Npn \@expl@push@filename@aux@@ #1#2#3
2822 {
2823   \__hook_curr_name_push:n {#3}
2824   \str_gset:Nx \g_file_curr_name_str {#3}
2825   #1 #2 {#3}
2826 }

```

(End of definition for `\SetDefaultHookLabel`, `\PushDefaultHookLabel`, and `\PopDefaultHookLabel`. These functions are documented on page 209.)

**`\UseHook`** Avoid the overhead of `xparse` and its protection that we don't want here (since the hook should vanish without trace if empty)!

**`\UseOneTimeHook`**

**`\UseHookWithArguments`**

**`\UseOneTimeHookWithArguments`**

```

2827 <latexrelease>\IncludeInRelease{2023/06/01}{\UseHookWithArguments}
2828 <latexrelease> {Hooks-with-args}
2829 \cs_new:Npn \UseHook { \hook_use:n }
2830 \cs_new:Npn \UseOneTimeHook { \hook_use_once:n }
2831 \cs_new:Npn \UseHookWithArguments { \hook_use:nnw }
2832 \cs_new:Npn \UseOneTimeHookWithArguments { \hook_use_once:nnw }
2833 <latexrelease>\EndIncludeInRelease
2834 <latexrelease>\IncludeInRelease{2020/10/01}{\UseHookWithArguments}
2835 <latexrelease> {Hooks-with-args}
2836 <latexrelease>\cs_new:Npn \UseHookWithArguments #1 #2 { }
2837 <latexrelease>\cs_new:Npn \UseOneTimeHookWithArguments #1 #2 { }
2838 <latexrelease>\EndIncludeInRelease

```

(End of definition for `\UseHook` and others. These functions are documented on page 203.)

**`\ShowHook`**

**`\LogHook`**

```

2839 \cs_new_protected:Npn \ShowHook { \hook_show:n }
2840 \cs_new_protected:Npn \LogHook { \hook_log:n }

```

(End of definition for `\ShowHook` and `\LogHook`. These functions are documented on page 212.)

**`\DebugHooksOn`**

**`\DebugHooksOff`**

```

2841 \cs_new_protected:Npn \DebugHooksOn { \hook_debug_on: }
2842 \cs_new_protected:Npn \DebugHooksOff { \hook_debug_off: }

```

(End of definition for `\DebugHooksOn` and `\DebugHooksOff`. These functions are documented on page 213.)

**`\DeclareHookRule`**

```

2843 \NewDocumentCommand \DeclareHookRule { m m m m }
2844 { \hook_gset_rule:nnnn {#1}{#2}{#3}{#4} }

```

(End of definition for `\DeclareHookRule`. This function is documented on page 210.)

**`\DeclareDefaultHookRule`** This declaration is only supported before `\begin{document}`.

```
2845 \NewDocumentCommand \DeclareDefaultHookRule { m m m }
2846         { \hook_gset_rule:nnnn {??}{#1}{#2}{#3} }
2847 \AtOnlyPreamble\DeclareDefaultHookRule
```

(End of definition for `\DeclareDefaultHookRule`. This function is documented on page 211.)

**`\ClearHookRule`** A special setup rule that removes an existing relation. Basically `\_hook_rule_gclear:nnn` plus fixing the property list for debugging.

*FMi: Needs perhaps an L3 interface, or maybe it should get dropped?*

```
2848 \NewDocumentCommand \ClearHookRule { m m m }
2849 { \hook_gset_rule:nnnn {#1}{#2}{unrelated}{#3} }
```

(End of definition for `\ClearHookRule`. This function is documented on page 210.)

**`\IfHookEmptyTF`** Here we avoid the overhead of `xparse`, since `\IfHookEmptyTF` is used in `\end` (that is, every L<sup>A</sup>T<sub>E</sub>X environment). As a further optimization, use `\let` rather than `\def` to avoid one expansion step.

**`\IfHookEmptyT`**  
**`\IfHookEmptyF`**

```
2850 \cs_new_eq:NN \IfHookEmptyTF \hook_if_empty:nTF
2851 \cs_new_eq:NN \IfHookEmptyT \hook_if_empty:nT
2852 \cs_new_eq:NN \IfHookEmptyF \hook_if_empty:nF
```

(End of definition for `\IfHookEmptyTF`, `\IfHookEmptyT`, and `\IfHookEmptyF`. These functions are documented on page 212.)

**`\IfHookExistsTF`** Marked for removal and no longer documented in the doc section!

*PhO: `\IfHookExistsTF` is used in `jlreq.cls`, `pxatbegshi.sty`, `pxeveryssel.sty`, `pxeveryshi.sty`, so the public name may be an alias of the internal conditional for a while. Regardless, those packages' use for `\IfHookExistsTF` is not really correct and can be changed.*

```
2853 \cs_new_eq:NN \IfHookExistsTF \_hook_if_usable:nTF
```

(End of definition for `\IfHookExistsTF`.)

## 4.13 Deprecated that needs cleanup at some point

**`\hook_disable:n`** Deprecated.

**`\hook_provide:n`** **`\cs_new_protected:Npn \hook_disable:n`**

```
2854 \cs_new_protected:Npn \hook_disable:n

2920   Use~\iow_char:N\|#2~instead.
2921 }

```

(End of definition for `\_hook_deprecated_warn:nn`.)

#### 4.14 Internal commands needed elsewhere

Here we set up a few horrible (but consistent) L<sup>A</sup>T<sub>E</sub>X<sub>2 $\epsilon$</sub>  names to allow for internal commands to be used outside this module. We have to unset the `@@` since we want double “at” sign in place of double underscores.

```

2922 <@@=

```

```

\@expl@@@initialize@all@@
\@expl@@@hook@curr@name@pop@@
2923 \cs_new_eq:NN \@expl@@@initialize@all@@
2924   \_hook_initialize_all:
2925 \cs_new_eq:NN \@expl@@@hook@curr@name@pop@@
2926   \_hook_curr_name_pop:

```

(End of definition for `\@expl@@@initialize@all@@` and `\@expl@@@hook@curr@name@pop@@`.)

Rolling back here doesn’t undefine the interface commands as they may be used in packages without rollback functionality. So we just make them do nothing which may or may not work depending on the code usage.

```

2927 %

## File 09

# ltxcmdhooks.dtx

## 1 Introduction

This file implements generic hooks for (arbitrary) commands. In theory every command `\<name>` offers now two associated hooks to which code can be added using `\AddToHook`,<sup>13</sup> `\AddToHookNext`, `\AddToHookWithArguments`, and `\AddToHookNextWithArguments`.<sup>14</sup>

However, this is only true “in theory”. In practice there are a number of restrictions that makes it impossible to use such generic command hooks in a number of cases, so please read all of section 2 to understand what may prevent you from using them successfully.

The generic command hooks are:

**cmd/<name>/before** This hook is executed at the very start of the command, right after its arguments (if any) are parsed. The hook `<code>` runs in the command inside a call to `\UseHookWithArguments`. Any code added to this hook using `\AddToHookWithArguments` or `\AddToHookNextWithArguments` can access the command’s arguments using `#1`, `#2`, etc., up to the number of arguments of the command. If `\AddToHook` or `\AddToHookNext` are used, the arguments cannot be accessed (see the `lthooks` documentation<sup>15</sup> on hooks with arguments).

**cmd/<name>/after** This hook is similar to **cmd/<name>/before**, but it is executed at the very end of the command body. This hook is implemented as a reversed hook.

The hooks are not physically present before `\begin{document}`<sup>16</sup> (i.e., using a command in the preamble will never execute the hook) and if nobody has declared any code for them, then they are not added to the command code ever. For example, if we have the following definition

```
\newcommand\foo[2]{Code #1 for #2!}
```

then executing `\foo{A}{B}` will simply run `Code_A_for_B!` as it was always the case. However, if somebody, somewhere (e.g., in a package) adds

```
\AddToHook{cmd/foo/before}{<before code>}
```

then, after `\begin{document}` the definition of `\foo` will be:

```
\renewcommand\foo[2]{%
  \UseHookWithArguments{cmd/foo/before}{2}{#1}{#2}%
  Code #1 for #2!}
```

and similarly `\AddToHook{cmd/foo/after}{<after code>}` alters the definition to

---

<sup>13</sup>In this documentation, when something is being said about `\AddToHook`, the same will be valid for `\AddToHookWithArguments`, unless that particular paragraph is highlighting the differences between both. The same is true for the other hook-related functions and their `...WithArguments` counterparts.

<sup>14</sup>In practice this is not supported for all types of commands, see section 2.2 for the restrictions that apply and what happens if one tries to use this with commands for which this is not supported.

<sup>15</sup>`texdoc lthooks-doc`

<sup>16</sup>More specifically, they are inserted in the commands after the `\begin{document}` hook, so they are also not present while `LATEX` is reading the `.aux` file.

```

\renewcommand\foo[2]{%
  Code #1 for #2!%
  \UseHookWithArguments{cmd/foo/after}{2}{#1}{#2}}

```

In other words, the mechanism is similar to what `etoolbox` offers with `\pretocmd` and `\apptocmd` with the important differences

- that code can be prepended or appended (i.e., added to the hooks) even if the command itself is not (yet) defined, because the defining package has not been loaded at this point;
- and that by using the hook management interface it is now possible to define how the code chunks added in these places are ordered, if different packages want to add code at these points.

## 2 Restrictions and Operational details

Adding arbitrary material to commands is tricky because most of the time we do not know what the macro expects as arguments when expanding and  $\text{\TeX}$  doesn't have a reliable way to see that, so some guesswork has to be employed.

We can do this in most cases when commands are defined using `\NewDocumentCommand` or `\newcommand` (with a few exceptions). For commands defined with `\def` the situation is less good. Common cases where the command hooks will not work are:

- Commands that use special catcode settings within their definition. In that case it is usually not possible to augment the definition (see 2.1).
- If a command is defined while `\ExplSyntaxOn` is in force **and** the command contains `~` characters to represent spaces, then it can't be patched to include the command hooks. In fact in some very special circumstances you might even get a low-level error rather than the information that the command can't be patched (see, for example, <https://github.com/latex3/latex2e/issues/1430>).
- Commands that have arguments as far as the user is concerned (e.g., `\section` or `\caption`), but are defined in a way that these arguments are not read by the user level command but only later during the processing. In that case the `after` hook doesn't work at all. The before hook only works with `\AddToHook` but not with `\AddToHookWithArguments` because the arguments haven't been read at that point where the hook is patched in. See section 2.2.
- Adding a specific generic command hook is only attempted once per command, thus after redefining a command such hooks will no longer be there and will also not being re-added, see section 2.1.1.

All this means that you have to have a good understanding of how commands are defined when you attempt to make use of such hooks and something goes wrong. What can help in that case is to turn on `\DebugHooksOn` in which case you get much more (low-level) details on why something fails and what was tried to enable the hooks.

## 2.1 Patching

The code here tries to find out if a command was defined with `\newcommand` or `\DeclareRobustCommand` or `\NewDocumentCommand`, and if so it *assumes* that the argument specification of the command is as expected (which is not fail-proof, if someone redefines the internals of these commands in devious ways, but is a reasonable assumption).

If the command is one of the defined types, the code here does a sandboxed expansion of the command such that it can be redefined again exactly as before, but with the hook code added.

If however the command is not a known type (it was defined with `\def`, for example), then the code uses an approach similar to `etoolbox`'s `\patchcmd` to retokenize the command with the hook code in place. This procedure, however, is more likely to fail if the catcode settings are not the same as the ones at the time of command's definition, so not always adding a hook to a command will work.

### 2.1.1 Timing

When `\AddToHook` (or its `expl3` equivalent) is called with a generic `cmd` hook, say, `cmd/foo/before`, for the first time (that is, no code was added to that same hook before), in the preamble of a document, it will store a patch instruction for that command until `\begin{document}`, and only then all the commands which had hooks added will be patched in one go. That means that no command in the preamble will have hooks patched into them.

At `\begin{document}` all the delayed patches will be executed, and if the command doesn't exist the code is still added to the hook, but it will not be executed. After `\begin{document}`, when `\AddToHook` is called with a generic `cmd` hook the first time, the command will be immediately patched to include the hook, and if it doesn't exist or if it can't be patched for any reason, an error is thrown; if `\AddToHook` was already used in the preamble no new patching is attempted.

This has the consequence that a command defined or redefined after `\begin{document}` only uses generic `cmd` hook code if `\AddToHook` is called for the first time after the definition is made, or if the command explicitly uses the generic hook in its definition by declaring it with `\NewHookPair` adding `\UseHook` as part of the code.<sup>17</sup>

## 2.2 Commands that look ahead

Some commands are defined in different “steps” and they look ahead in the input stream to find more arguments. If you try to add some code to the `cmd/<name>/after` hook of such command, it will not work, and it is not possible to detect that programmatically, so the user has to know (or find out) which commands can or cannot have hooks attached to them.

One good example is the `\section` command. You can add something to the `cmd/section/before` hook (but only with `\AddToHook` not `\AddToHookWithArguments`), but if you try to add anything to the `cmd/section/after` hook, `\section` will no longer work at all. That happens because the `\section` macro takes no argument, but instead calls a few internal `LATEX` macros to look for the optional and mandatory arguments. By adding code to the `cmd/section/after` hook, you get in the way of that scanning.

---

<sup>17</sup>We might change this behavior in the main document slightly after gaining some usage experience.

In such a case, where it is known that a specific generic command hook does not work if code is added to it, the package author can add a `\DisableGenericHook`<sup>18</sup> declaration to prevent this from happening in user documents and thereby avoiding obscure errors.

### 3 Package Author Interface

The `cmd` hooks are, by default, available for all commands that can be patched to add the hooks. For some commands, however, the very beginning or the very end of the code is not the best place to put the hooks, for example, if the command looks ahead for arguments (see section 2.2).

If you are a package author and you want to add the hooks to your own commands in the proper position you can define the command and manually add the `\UseHookWithArguments` calls inside the command in the proper positions, and manually define the hooks with `\NewHookWithArguments` or `\NewReversedHookWithArguments`. When the hooks are explicitly defined, patching is not attempted so you can make sure your command works properly. For example, an (admittedly not really useful) command that typesets its contents in a framed box with width optionally given in parentheses:

```
\newcommand\fancybox{\@ifnextchar({\@fancybox}{\@fancybox(5cm)}}
\def\@fancybox(#1)#2{\fbox{\parbox{#1}{#2}}}
```

If you try that definition, then add some code after it with

```
\AddToHook{cmd/fancybox/after}{<code>}
```

and then use the `\fancybox` command you will see that it will be completely broken, because the hook will get executed in the middle of parsing for optional (...) argument.

If, on the other hand, you want to add hooks to your command you can do something like:

```
\newcommand\fancybox{\@ifnextchar({\@fancybox}{\@fancybox(5cm)}}
\def\@fancybox(#1)#2{\fbox{%
    \UseHookWithArguments{cmd/fancybox/before}{2}{#1}{#2}%
    \parbox{#1}{#2}%
    \UseHookWithArguments{cmd/fancybox/after}{2}{#1}{#2}}}
\NewHookWithArguments{cmd/fancybox/before}{2}
\NewReversedHookWithArguments{cmd/fancybox/after}{2}
```

then the hooks will be executed where they should and no patching will be attempted. It is important that the hooks are declared with `\NewHookWithArguments` or `\NewReversedHookWithArguments`, otherwise the command hook code will try to patch the command. Note also that the call to `\UseHookWithArguments{cmd/fancybox/before}` does not need to be in the definition of `\fancybox`, but anywhere it makes sense to insert it (in this case in the internal `\@fancybox`).

Alternatively, if for whatever reason your command does not support the generic hooks provided here, you can disable a hook with `\DisableGenericHook`<sup>19</sup>, so that when someone tries to add code to it they will get an error. Or if you don't want the error, you can simply declare the hook with `\NewHook` and never use it.

<sup>18</sup>Please use `\DisableGenericHook` if at all, only on hooks that you “own”, i.e., for commands your package or class defines and not second guess whether or not hooks of other packages should get disabled!

<sup>19</sup>Please use `\DisableGenericHook` if at all, only on hooks that you “own”, i.e., for commands your package or class defines and not second guess whether or not hooks of other packages should get disabled!

The above approach is useful for really complex commands where for one or the other reason the hooks can't be placed at the very beginning and end of the command body and some hand-crafting is needed. However, in the example above the real (and in fact only) issue is the cascading argument parsing in the style developed long ago in L<sup>A</sup>T<sub>E</sub>X 2.09. Thus, a much simpler solution for this case is to replace it with the modern `\NewDocumentCommand` syntax and define the command as follows:

```
\DeclareDocumentCommand\fancybox{D() {5cm}m}{\fbox{\parbox{#1}{#2}}}
```

If you do that then both hooks automatically work and are patched into the right places.

### 3.1 Arguments and redefining commands

The code in `ltxcmdhooks` does its best to find out how many arguments a given command has, and to insert the appropriate call to `\UseHookWithArguments`, so that the arguments seen by the hook are exactly those grabbed by the command (the hook, after all, is a macro call, so the arguments have to be placed in the right order, or they won't match).

When using the package writer interface, as discussed in section 3, to change the position of the hooks in your commands, you are also free to change how the hook code in your command sees its arguments. When a `cmd` hook is declared with `\NewHook` (or `\NewHookWithArguments` or other variations of that), it loses its “generic” nature and works as a regular hook. This means that you may choose to declare it without arguments regardless if the command takes arguments or not, or declare it with arguments, even if the command takes none.

However, this flexibility should not be abused. When using a nonstandard configuration for the hook arguments, think reasonably: a user will expect that the argument `#1` in the hook corresponds to the argument's first argument, and so on. Any other configuration is likely to cause confusion and, if used, will have to be well documented.

This flexibility, however, allows you to “correct” the arguments for the hooks. For example, L<sup>A</sup>T<sub>E</sub>X's `\refstepcounter` has a single argument, the name of the counter. The `cleveref` package adds an optional argument to `\refstepcounter`, making the name of the counter argument `#2`. If the author of `cleveref` wanted, for whatever reason, to add hooks to `\refstepcounter`, to preserve compatibility he could write something along the lines of:

```
\NewHookWithArguments{cmd/refstepcounter/before}{1}
\renewcommand\refstepcounter[2][<default>]{%
  \UseHookWithArguments{cmd/refstepcounter/before}{1}{#2}%
  <code for \refstepcounter>}
```

so that the mandatory argument, which is arg `#2` in the definition, would still be seen as `#1` in the hook code.

Another possibility would be to place the optional argument as the second argument for the hook, so that people looking for it would be able to use it. In either case, it would have to be well documented to cause as little confusion as possible.

## 4 The Implementation

### 4.1 Execution plan

To add `before` and `after` hooks to a command we will need to peek into the definition of a command, which is always a tricky thing to do. Some cases are easy because we

know how the command was defined, so we can assume how its  $\langle parameter\ text \rangle$  looks like (for example a command defined with `\newcommand` may have an optional argument followed by a run of mandatory arguments), so we can just expand that command and make it grab `#1`, `#2`, etc. as arguments and define it all back with the hooks added.

Life’s usually not that easy, so with some commands we can’t do that (a `#1` might as well be `#12112` instead of the expected `#6112`, for example) so we need to resort to “patching” the command: read its `\meaning`, and tokenize it again with `\scantokens` and hope for the best.

So the overall plan is:

1. Check if a command is of a known type (that is, defined with `\newcommand`<sup>20</sup>, `\DeclareRobustCommand`, or `\New(Expandable)DocumentCommand`), and if is, take appropriate action.
2. If the command is not a known type, we’ll check if the command can be patched. Two things will prevent a command from being patched: if it was defined in a nonstandard catcode setting, or if it is an internal `expl3` command with `__\module` in its name, in which case we refuse to patch.
3. If the command was defined in nonstandard catcode settings, we will try a few standard ones to try our best to carry out the patching. If this doesn’t help either, the code will give up and throw an error.

```

1 <@@=hook>
2 <*2ekernel | latexrelease>
3 \ExplSyntaxOn
4 <latexrelease> \NewModuleRelease{2021/06/01}{ltxcmdhooks}
5 <latexrelease> {The-hook-management-system-for-commands}
```

## 4.2 Variables

`\g_hook_patch_action_list_tl` Pairs of `\if<cmd>..\patch<cmd>` to be used with `\robust@command@act` when looking for a known patching rule. This token list is exposed because we see some future applications (with very specialized packages, such as `etoolbox` that may want to extend the pairs processed. It is not meant for general use which is why it is not documented in the interface documentation above.

```
6 \tl_new:N \g_hook_patch_action_list_tl
```

(End of definition for `\g_hook_patch_action_list_tl`.)

`\l__hook_patch_num_args_int` The number of arguments in a macro being patched.

```
7 \int_new:N \l__hook_patch_num_args_int
```

(End of definition for `\l__hook_patch_num_args_int`.)

`\l__hook_patch_prefixes_tl` The prefixes and parameters of the definition for the macro being patched.

```

8 \tl_new:N \l__hook_patch_prefixes_tl
9 \tl_new:N \l__hook_param_text_tl
10 \tl_new:N \l__hook_replace_text_tl
```

<sup>20</sup>It’s not always possible to reliably detect this case because a command defined with no optional argument is indistinguishable from a `\defed` command.

(End of definition for `\l__hook_patch_prefixes_tl`, `\l__hook_param_text_tl`, and `\l__hook_replace_text_tl`.)

`\c__hook_hash_tl` `\c__hook_hashes_tl` Two constant token lists that contain one and two parameter tokens.

```
11 \tl_const:Nn \c__hook_hash_tl { # }
12 \tl_const:Nn \c__hook_hashes_tl { # # }
```

(End of definition for `\c__hook_hash_tl` and `\c__hook_hashes_tl`.)

`\__hook_exp_not:NN` `\__hook_def_cmd:w` Two temporary macros that change depending on the macro being patched.

```
13 \cs_new_eq:NN \__hook_exp_not:NN ?
14 \cs_new_eq:NN \__hook_def_cmd:w ?
```

(End of definition for `\__hook_exp_not:NN` and `\__hook_def_cmd:w`.)

`\q__hook_recursion_tail` `\q__hook_recursion_stop` Internal quarks for recursion: they can't appear in any macro being patched.

```
15 \quark_new:N \q__hook_recursion_tail
16 \quark_new:N \q__hook_recursion_stop
```

(End of definition for `\q__hook_recursion_tail` and `\q__hook_recursion_stop`.)

`\g__hook_delayed_patches_prop` A list containing the patches delayed to `\begin{document}`, so that patching is not attempted twice.

```
17 \prop_new:N \g__hook_delayed_patches_prop
```

(End of definition for `\g__hook_delayed_patches_prop`.)

`\__hook_patch_debug:x` A helper for patching debug info.

```
18 \cs_new_protected:Npn \__hook_patch_debug:x #1
19 { \__hook_debug:n { \iow_term:x { [lthooks]~#1 } } }
```

(End of definition for `\__hook_patch_debug:x`.)

### 4.3 Variants

`\tl_rescan:nV` `expl3` function variants used throughout the code.

```
20 \cs_generate_variant:Nn \tl_rescan:nn { nV }
```

(End of definition for `\tl_rescan:nV`.)

### 4.4 Patching or delaying

Before `\begin{document}` all patching is delayed.

`\__hook_try_put_cmd_hook:n` `\__hook_try_put_cmd_hook:w` This function is called from within `\AddToHook`, when code is first added to a generic `cmd` hook. If it is called within in the preamble, it delays the action until `\begin{document}`; otherwise it tries to update the hook.

```
21 <latexrelease>\IncludeInRelease{2024/12/22}{\__hook_try_put_cmd_hook:n}%
22 <latexrelease>{Don't~define~command}
23 \cs_new_protected:Npn \__hook_try_put_cmd_hook:n #1
24 { \__hook_try_put_cmd_hook:w #1 / / / \s__hook_mark {#1} }
25 \cs_new_protected:Npn \__hook_try_put_cmd_hook:w
26 #1 / #2 / #3 / #4 \s__hook_mark #5
27 {
28 \__hook_debug:n { \iow_term:n { ->~Adding~cmd~hook~to~'~#2'~(~#3): } } }
```

`\__hook_patch_cmd_or_delay:Nnn` expects the command to be patched as its first argument so we need to construct it from its name (`#2`). However, at this moment it may not exist yet, so using `\cs:w` would incorrectly turn it from “undefined” into `\relax`. We therefore use the following curious construction: we start a group and expand out of it to call `\cs:w`. If the command is now changed to `\relax` the `\group_end:` will undo that change, but the token is nevertheless there to be consumed by `\__hook_patch_cmd_or_delay:Nnn`.

```

29   \group_begin:
30   \exp_after:wN
31   \group_end:
32   \exp_after:wN
33   \__hook_patch_cmd_or_delay:Nnn
34   \cs:w #2\cs_end:
35   {#2} {#3}
36 }
37 <latexrelease>\EndIncludeInRelease

38 <latexrelease>\IncludeInRelease{2021/11/15}{\__hook_try_put_cmd_hook:n}%
39 <latexrelease>           {Standardise-generic-hook-names}
40 <latexrelease>\cs_new_protected:Npn \__hook_try_put_cmd_hook:n #1
41 <latexrelease> { \__hook_try_put_cmd_hook:w #1 / / / \s__hook_mark {#1} }
42 <latexrelease>\cs_new_protected:Npn \__hook_try_put_cmd_hook:w
43 <latexrelease>    #1 / #2 / #3 / #4 \s__hook_mark #5
44 <latexrelease> {
45 <latexrelease>    \__hook_debug:n { \iow_term:n { ->~Adding~cmd~hook~to~'~#2'~(#3): } }
46 <latexrelease>    \exp_args:Nc \__hook_patch_cmd_or_delay:Nnn {#2} {#2} {#3}
47 <latexrelease> }
48 <latexrelease>\EndIncludeInRelease

49 <latexrelease>\IncludeInRelease{2021/06/01}{\__hook_try_put_cmd_hook:n}%
50 <latexrelease>           {Standardise-generic-hook-names}
51 <latexrelease>\cs_new_protected:Npn \__hook_try_put_cmd_hook:n #1
52 <latexrelease> { \__hook_try_put_cmd_hook:w #1 / / / \s__hook_mark {#1} }
53 <latexrelease>\cs_new_protected:Npn \__hook_try_put_cmd_hook:w
54 <latexrelease>    #1 / #2 / #3 / #4 \s__hook_mark #5
55 <latexrelease> {
56 <latexrelease>    \__hook_debug:n { \iow_term:n { ->~Adding~cmd~hook~to~'~#2'~(#3): } }
57 <latexrelease>    \str_case:nnTF {#3}
58 <latexrelease>        { { before } { } } { after } { } }
59 <latexrelease>    { \exp_args:Nc \__hook_patch_cmd_or_delay:Nnn {#2} {#2} {#3} }
60 <latexrelease>    { \msg_error:nnnn { hooks } { wrong-cmd-hook } {#2} {#3} }
61 <latexrelease> }
62 <latexrelease>\EndIncludeInRelease

```

(End of definition for `\__hook_try_put_cmd_hook:n` and `\__hook_try_put_cmd_hook:w`.)

`\__hook_patch_cmd_or_delay:Nnn`  
`\__hook_cmd_begindocument_code:`

In the preamble, `\__hook_patch_cmd_or_delay:Nnn` just adds the patch instruction to a property list to be executed later.

```

63 \cs_new_protected:Npn \__hook_patch_cmd_or_delay:Nnn #1 #2 #3
64 {
65   \__hook_debug:n { \iow_term:n { ->~Add~generic~cmd~hook~for~#2~(#3). } }
66   \__hook_debug:n
67   { \iow_term:n { !~In~the~preamble:~delaying. } }
68   \prop_gput:Nnn \g__hook_delayed_patches_prop { #2 / #3 }
69   { \__hook_cmd_try_patch:nn {#2} {#3} }

```

70 }

The delayed patches are added to a property list to prevent duplication, and the code stored in the property list for each key is executed. The function `\__hook_patch_cmd_or_delay:Nnn` is also redefined to be `\__hook_patch_command:Nnn` so that no further delaying is attempted.

```
71 \cs_new_protected:Npn \__hook_cmd_begindocument_code:
72 {
73   \cs_gset_eq:NN \__hook_patch_cmd_or_delay:Nnn \__hook_patch_command:Nnn
74   \prop_map_function:NN \g__hook_delayed_patches_prop { \use_i:nn }
75   \prop_gclear:N \g__hook_delayed_patches_prop
76   \cs_undefine:N \__hook_cmd_begindocument_code:
77 }
78 \g@addto@macro \@kernel@after@begindocument
79 { \__hook_cmd_begindocument_code: }
```

(End of definition for `\__hook_patch_cmd_or_delay:Nnn` and `\__hook_cmd_begindocument_code:.`)

`\__hook_cmd_try_patch:nn`

At `\begin{document}` tries patching the command if the hook was not manually created in the meantime. If the document does not exist, no error is raised here as it may hook into a package that wasn't loaded. Hooks added to commands in the document body still raise an error if the command is not defined.

```
80 \cs_new_protected:Npn \__hook_cmd_try_patch:nn #1 #2
81 {
82   \__hook_debug:n
83   { \iow_term:x { ->~\string\begin{document}-try-cmd / #1 / #2. } }
84   \__hook_if_declared:nTF { cmd / #1 / #2 }
85   {
86     \__hook_debug:n
87     { \iow_term:n { .->~Giving-up:~hook~already~created. } }
88   }
89   {
90     \cs_if_exist:cT {#1}
91     { \exp_args:Nc \__hook_patch_command:Nnn {#1} {#1} {#2} }
92   }
93 }
```

(End of definition for `\__hook_cmd_try_patch:nn.`)

## 4.5 Patching commands

`\__hook_patch_command:Nnn`  
`\__hook_patch_check:NNnn`  
`\__hook_if_public_command:NTF`  
`\__hook_if_public_command:w`

`\__hook_patch_command:Nnn` will do some sanity checks on the argument to detect if it is possible to add hooks to the command, and raises an error otherwise. If the command can contain hooks, then it uses `\robust@command@act` to find out what type is the command, and patch it accordingly.

```
94 \cs_new_protected:Npn \__hook_patch_command:Nnn #1 #2 #3
95 {
96   \__hook_patch_debug:x { analyzing~'\token_to_str:N #1' }
97   \__hook_patch_debug:x { \token_to_str:N #1 = \token_to_meaning:N #1 }
98   \__hook_patch_check:NNnn \cs_if_exist:NTF #1 { undef }
99   {
100     \__hook_patch_debug:x { ++~control~sequence~is~defined }
101     \__hook_patch_check:NNnn \token_if_macro:NTF #1 { macro }
102     {
```

```

103         \__hook_patch_debug:x { ++~control~sequence~is~a~macro }
104         \__hook_patch_check:NNnn \__hook_if_public_command:NTF #1 { expl3 }
105         {
106             \__hook_patch_debug:x { ++~macro~is~not~private }
107             \robust@command@act
108             \g_hook_patch_action_list_tl #1
109             \__hook_retokenize_patch:Nnn { #1 {#2} {#3} }
110         }
111     }
112 }
113 }

```

And here's the auxiliary used above:

```

114 \cs_new_protected:Npn \__hook_patch_check:NNnn #1 #2 #3 #4
115 {
116     #1 #2 {#4}
117     {
118         \msg_error:nxxx { hooks } { cant-patch }
119         { \token_to_str:N #2 } {#3}
120     }
121 }

```

and a conditional `\__hook_if_public_command:NTF` to check if a command has `__` in its name (no other checking is performed). Primitives with `:D` in their name could be included here, but they are already discarded in the `\token_if_macro:NTF` test above.

```

122 \use:x
123 {
124     \prg_new_protected_conditional:Npnn
125     \exp_not:N \__hook_if_public_command:N ##1 { TF }
126     {
127         \exp_not:N \exp_last_unbraced:Nf
128         \exp_not:N \__hook_if_public_command:w
129         { \exp_not:N \cs_to_str:N ##1 }
130         \tl_to_str:n { _ _ } \s__hook_mark
131     }
132 }
133 \exp_last_unbraced:NNNno
134 \cs_new_protected:Npn \__hook_if_public_command:w
135     #1 \tl_to_str:n { _ _ } #2 \s__hook_mark
136 {
137     \tl_if_empty:nTF {#2}
138     { \prg_return_true: }
139     { \prg_return_false: }
140 }

```

*(End of definition for `\__hook_patch_command:Nnn` and others.)*

#### 4.5.1 Patching by expansion and redefinition

`\g_hook_patch_action_list_tl` This is the list of known command types and the function that patches the command hooks into them. The conditionals are taken from `\ShowCommand`, `\NewCommandCopy` and `\__kernel_cmd_if_xparse:NTF` defined in `ltxcmd`.

```

141 \tl_gset:Nn \g_hook_patch_action_list_tl
142 {
143     { \@if@DeclareRobustCommand \__hook_patch_DeclareRobustCommand:Nnn }

```

```

144     { \@ifnewcommand \__hook_patch_newcommand:Nnn }
145     { \__kernel_cmd_if_xparse:NTF \__hook_cmd_patch_xparse:Nnn }
146   }

```

(End of definition for \g\_hook\_patch\_action\_list\_tl.)

\\_\_hook\_patch\_DeclareRobustCommand:Nnn

At this point we know that the commands can be patched by expanding then redefining. These are the cases of commands defined with \newcommand with an optional argument or with \DeclareRobustCommand.

With \\_\_hook\_patch\_DeclareRobustCommand:Nnn we check if the command has an optional argument (with a test counter-intuitively called \@ifnewcommand; also make sure the command doesn't take args by calling \robust@command@chk@safe). If so, we pass the patching action to \\_\_hook\_patch\_newcommand:Nnn, otherwise we call the patching engine \\_\_hook\_patch\_expand\_redefine:NNnn with a \c\_false\_bool to indicate that there is no optional argument.

```

147 \cs_new_protected:Npn \__hook_patch_DeclareRobustCommand:Nnn #1
148   {
149     \exp_args:Nc \__hook_patch_DeclareRobustCommand_aux:Nnn
150     { \cs_to_str:N #1 ~ }
151   }
152 \cs_new_protected:Npn \__hook_patch_DeclareRobustCommand_aux:Nnn #1
153   {
154     \robust@command@chk@safe #1
155     { \@ifnewcommand #1 }
156     { \use_ii:nn }
157     { \__hook_patch_newcommand:Nnn }
158     { \__hook_patch_expand_redefine:NNnn \c_false_bool }
159     #1
160   }

```

(End of definition for \\_\_hook\_patch\_DeclareRobustCommand:Nnn.)

\\_\_hook\_patch\_newcommand:Nnn

If the command was defined with \newcommand and an optional argument, call the patching engine with a \c\_true\_bool to flag the presence of an optional argument, and with \command to patch the actual code for \command.

```

161 \cs_new_protected:Npn \__hook_patch_newcommand:Nnn #1
162   {
163     \exp_args:NNc \__hook_patch_expand_redefine:NNnn \c_true_bool
164     { \c_backslash_str \cs_to_str:N #1 }
165   }

```

(End of definition for \\_\_hook\_patch\_newcommand:Nnn.)

\\_\_hook\_cmd\_patch\_xparse:Nnn

And for commands defined by the xparse commands use this for patching:

```

166 \cs_new_protected:Npn \__hook_cmd_patch_xparse:Nnn #1
167   {
168     \exp_args:NNc \__hook_patch_expand_redefine:NNnn \c_false_bool
169     { \cs_to_str:N #1 ~ code }
170   }

```

(End of definition for \\_\_hook\_cmd\_patch\_xparse:Nnn.)

```

\__hook_patch_expand_redefine:NNnn
\__hook_redefine_with_hooks:NNnn
\__hook_make_prefixes:w

```

Now the real action begins. Here we have in #1 a boolean indicating if the command has a leading [...] delimited argument, in #2 the command control sequence, in #3 the name of the command (note that #1  $\neq$  \csname#2\endcsname at this point!), and in #4 the hook position, either **before** or **after**.

Patching with expansion+redefinition is trickier than it looks like at first glance. Suppose the simple definition:

```
\def\foo#1{#1##2}
```

When defined, its *<replacement text>* will be a token list containing:

```
out_param 1, mac_param #, character 2
```

Then, after expanding \foo{##1} (here ## denotes a single #6) we end up with a token list with *out\_param 1* replaced:

```
mac_param #, character 1, mac_param #, character 2
```

that is, the definition would be:

```
\def\foo#1{#1#2}
```

which obviously fails, because the original input in the definition was ## but T<sub>E</sub>X reduced that to a single parameter token #6 when carrying out the definition. That leaves no room for a clever solution with (say) \unexpanded, because anything that would double the second #6, would also (incorrectly) double the first, so there's not much to do other than a manual solution.

There are three cases we can distinguish to make things hopefully faster on simpler cases:

1. a macro with no parameters;
2. a macro with no parameter tokens in its definition;
3. a macro with parameters *and* parameter tokens.

The first case is trivial: if the macro has no parameters, we can just use \unexpanded around it, and if there is a parameter token in it, it is handled correctly (the macro can be treated as a t<sub>l</sub> variable).

The second case requires looking at the *<replacement text>* of the macro to see if it has a parameter token in there. If it does not, then there is no worry, and the macro can be redefined normally (without \unexpanded).

The third case, as usual, is the devious one. Here we'll have to loop through the definition token by token, and double every parameter token, so that this case can be handled like the previous one.

```

171 <latexrelease> \IncludeInRelease{2023/06/01}{\__hook_patch_expand_redefine:NNnn}
172 <latexrelease> {cmd~hooks~with~args}
173 \cs_new_protected:Npn \__hook_patch_expand_redefine:NNnn #1 #2 #3 #4
174 {
175   \__hook_patch_debug:x { ++~command~can~be~patched~without~rescanning }

```

We'll start by counting the number of arguments in the command by counting the number of characters in the `\cs_parameter_spec:N` of the macro, divided by two, and subtracting one if the command has an optional argument (that is, an extra `[]` in its `\parameter text`)).

```

176 \int_set:Nn \l__hook_patch_num_args_int
177 {
178   \exp_args:Nf \str_count:n { \__kernel_cs_parameter_spec:N #2 } / 2
179   \bool_if:NT #1 { -1 }
180 }

```

Now build two token lists:

`\l__hook_param_text_tl` will contain the `\parameter text` to be used when redefining the macro. It should be identical to the `\parameter text` used when originally defining that macro.

`\l__hook_replace_text_tl` will contain braced pairs of `\c__hook_hashes_tl<num>` to feed to the macro when expanded. This token list as well as the previous will have the first item surrounded by `[...]` in the case of an optional argument.

The use of `\c__hook_hashes_tl` here is to differentiate actual parameters in the macro from parameter tokens in the original definition of the macro. Later on, `\c__hook_hashes_tl` is either replaced by actual parameter tokens, or expanded into them.

```

181 \int_compare:nNnTF { \l__hook_patch_num_args_int } > { \c_zero_int }
182 {

```

We'll first check if the command has any parameter token in its definition (feeding it empty arguments), and set `\__hook_exp_not:n` accordingly. `\__hook_exp_not:n` will be used later to either leave `\c__hook_hashes_tl` or expand it, and also to remember the result of `\__hook_if_has_hash:nTF` to avoid testing twice (the test can be rather slow).

```

183   \tl_set:Nx \l__hook_tmpa_tl { \bool_if:NTF #1 { [] } { { } } }
184   \int_step_inline:nnn { 2 } { \l__hook_patch_num_args_int }
185   { \tl_put_right:Nn \l__hook_tmpa_tl { { } } }
186   \exp_args:NNo \exp_args:No \__hook_if_has_hash:nTF
187   { \exp_after:wN #2 \l__hook_tmpa_tl }
188   { \cs_set_eq:NN \__hook_exp_not:n \exp_not:n }
189   { \cs_set_eq:NN \__hook_exp_not:n \use:n }
190   \cs_set_protected:Npn \__hook_tmp:w ##1 ##2
191   {
192     ##1 \l__hook_param_text_tl { \use:n ##2 }
193     ##1 \l__hook_replace_text_tl { \__hook_exp_not:n {##2} }
194   }

```

Here we'll conditionally add `[...]` around the first parameter:

```

195   \bool_if:NTF #1
196   { \__hook_tmp:w \tl_set:Nx { [ \c__hook_hashes_tl 1 ] } }
197   { \__hook_tmp:w \tl_set:Nx { { \c__hook_hashes_tl 1 } } }

```

Then, for every parameter from the second, just add it normally:

```

198   \int_step_inline:nnn { 2 } { \l__hook_patch_num_args_int }
199   { \__hook_tmp:w \tl_put_right:Nx { { \c__hook_hashes_tl ##1 } } }

```

Now, if the command has any parameter token in its definition (then `\__hook_exp_not:n` is `\exp_not:n`), call `\__hook_double_hashes:n` to double them, and replace every `\c__hook_hashes_tl` by #:

```

200     \tl_set:Nx \l__hook_replace_text_tl
201     { \exp_not:N #2 \exp_not:V \l__hook_replace_text_tl }
202     \tl_set:Nx \l__hook_replace_text_tl
203     {
204         \token_if_eq_meaning:NNTF \__hook_exp_not:n \exp_not:n
205         { \exp_args:NNV \exp_args:No \__hook_double_hashes:n }
206         { \exp_args:NV \exp_not:o }
207         \l__hook_replace_text_tl
208     }

```

And now, set a few auxiliaries for the case that the macro has parameters, so it won't be passed through `\unexpanded` (twice):

```

209     \cs_set_eq:NN \__hook_def_cmd:w \tex_gdef:D
210     \cs_set_eq:NN \__hook_exp_not:NN \prg_do_nothing:
211 }
212 {

```

In the case the macro has no parameters, we'll treat it as a token list and things are much simpler (expansion control looks a bit complicated, but it's just a pair of `\exp_not:N` preventing another `\exp_not:n` from expanding):

```

213     \tl_clear:N \l__hook_param_text_tl
214     \tl_set_eq:NN \l__hook_replace_text_tl #2
215     \cs_set_eq:NN \__hook_def_cmd:w \tex_xdef:D
216     \cs_set:Npn \__hook_exp_not:NN ##1 { \exp_not:N ##1 \exp_not:N }
217 }

```

Before redefining, we need to also get the prefixes used when defining the command. Here we ensure that the `\escapechar` is printable, otherwise a macro defined with prefixes `\protected` `\long` will have it `\meaning` printed as `protectedlong`, making life unnecessarily complicated. Here the `\escapechar` is changed to `/`, then we loop between pairs of `/.../` extracting the prefixes.

```

218     \group_begin:
219     \int_set:Nn \tex_escapechar:D { '/' }
220     \use:x
221     {
222     \group_end:
223     \tl_set:Nx \exp_not:N \l__hook_patch_prefixes_tl
224     { \exp_not:N \__hook_make_prefixes:w \cs_prefix_spec:N #2 / / }
225     }

```

Here we redefine the hook to have the right number of arguments. Disabling the hook, undefining the `parameter` token list then calling `\__hook_make_usable:nn` are enough to redefine the hook to the extent we want. Code stored in the hook and other metadata about it are not lost in the process.

```

226     \__hook_disable:n { cmd / #3 / #4 }
227     \cs_undefine:c { c__hook_cmd / #3 / #4_parameter_tl }
228     \__hook_make_usable:nn { cmd / #3 / #4 } { \l__hook_patch_num_args_int }

```

Now call `\__hook_redefine_with_hooks:Nnnn` with the macro being redefined in #1, then `\UseHook{cmd/<name>/before}` in #2 or `\UseHook{cmd/<name>/after}` in #3 (one is always empty), and in #4 the *<replacement text>* of the macro.

```

229 \use:e
230 {
231   \_hook_redefine_with_hooks:Nnnn \exp_not:N #2
232   \str_if_eq:nnTF {#4} { after }
233   { \use_ii_i:nn }
234   { \use:nn }
235   { {
236     \_hook_exp_not:NN \exp_not:N \UseHookWithArguments
237     { cmd / #3 / #4 } { \int_use:N \l__hook_patch_num_args_int }
238     \_hook_braced_parameter:n { cmd / #3 / #4 }
239   } }
240   { { } }
241   { \_hook_exp_not:NN \exp_not:V \l__hook_replace_text_tl }
242 }

```

Finally, update the hook code.

```

243 \_hook_update_hook_code:n { cmd / #3 / #4 }
244 }
245 <latexrelease> \EndIncludeInRelease

310 <latexrelease> }
311 <latexrelease> }
312 <latexrelease> \EndIncludeInRelease

```

Now that all the needed tools are ready, without further ado we'll redefine the command. The definition uses the prefixes gathered in `\l__hook_patch_prefixes_tl`, a primitive `\__hook_def_cmd:w` (which is `\tex_gdef:D` or `\tex_xdef:D`) to avoid adding extra prefixes, and the `<parameter text>` from `\l__hook_param_text_tl`.

Then finally, in the body of the definition, we insert #2, which is `cmd/#1/before` or empty, #4 which is the `<replacement text>`, and #3 which is `cmd/#1/after` or empty.

```

313 \cs_new_protected:Npn \__hook_redefine_with_hooks:Nnnn #1 #2 #3 #4
314 {
315   \l__hook_patch_prefixes_tl
316   \exp_after:wN \__hook_def_cmd:w
317   \exp_after:wN #1 \l__hook_param_text_tl
318   { #2 #4 #3 }
319 }

```

Here's the auxiliary that makes the prefix control sequences for the redefinition. Each item has to be `\tl_trim_spaces:n`'d because the last item (and not any other) has a trailing space.

```

320 \cs_new:Npn \__hook_make_prefixes:w / #1 /
321 {
322   \tl_if_empty:nF {#1}
323   {
324     \exp_not:c { tex_ \tl_trim_spaces:n {#1} :D }

```

```

325     \__hook_make_prefixes:w /
326   }
327 }

```

(End of definition for \\_\_hook\_patch\_expand\_redefine:NNnn, \\_\_hook\_redefine\_with\_hooks:Nnnn, and \\_\_hook\_make\_prefixes:w.)

Here are some auxiliaries for the contraption above.

\\_\_hook\_if\_has\_hash\_p:n \\_\_hook\_if\_has\_hash:nTF searches the token list #1 for a catcode 6 token, and if any is found, it returns true, and false otherwise. The searching doesn't care about preserving groups or spaces: we can ignore those safely (braces are removed) so that searching is as fast as possible.

```

328 \prg_new_conditional:Npnn \__hook_if_has_hash:n #1 { TF }
329 { \__hook_if_has_hash:w #1 ## \s__hook_mark }
330 \cs_new:Npn \__hook_if_has_hash:w #1
331 {
332   \tl_if_single_token:nTF {#1}
333   {
334     \token_if_eq_catcode:NNTF ## #1
335     { \__hook_if_has_hash_check:w }
336     { \__hook_if_has_hash:w }
337   }
338   { \__hook_if_has_hash:w #1 }
339 }
340 \cs_new:Npn \__hook_if_has_hash_check:w #1 \s__hook_mark
341 { \tl_if_empty:nTF {#1} { \prg_return_false: } { \prg_return_true: } }

```

(End of definition for \\_\_hook\_if\_has\_hash:nTF, \\_\_hook\_if\_has\_hash:w, and \\_\_hook\_if\_has\_hash\_check:w.)

\\_\_hook\_double\_hashes:n \\_\_hook\_double\_hashes:w loops through the token list #1 and duplicates any catcode 6 token, and expands tokens \ifx-equal to \c\_\_hook\_hashes\_tl, and leaves all other tokens \notexpanded with \exp\_not:N. Unfortunately pairs of explicit catcode 1 and catcode 2 character tokens are normalised to {<sub>1</sub> and }<sub>1</sub> because it's not feasible to expandably detect the character code (*maybe* it could be done using something along the lines of <https://tex.stackexchange.com/a/527538>, but it's far too much work for close to zero benefit).

\\_\_hook\_double\_hashes:w is the tail-recursive loop macro, that tests which of the three types of item is in the head of the token list.

```

342 \cs_new:Npn \__hook_double_hashes:n #1
343 { \__hook_double_hashes:w #1 \q__hook_recursion_tail \q__hook_recursion_stop }
344 \cs_new:Npn \__hook_double_hashes:w #1 \q__hook_recursion_stop
345 {
346   \tl_if_head_is_N_type:nTF {#1}
347   { \__hook_double_hashes_output:N }
348   {
349     \tl_if_head_is_group:nTF {#1}
350     { \__hook_double_hashes_group:n }
351     { \__hook_double_hashes_space:w }
352   }
353   #1 \q__hook_recursion_stop
354 }

```

`\__hook_double_hashes_output:N` checks for the end of the token list, then checks if the token is `\c__hook_hashes_tl`, and if so just leaves it.

```

355 \cs_new:Npn \__hook_double_hashes_output:N #1
356 {
357   \if_meaning:w \q__hook_recursion_tail #1
358   \__hook_double_hashes_stop:w
359   \fi:
360   \if:w ?
361     \if_meaning:w \c__hook_hash_tl #1 ! \fi:
362     \if_meaning:w \c__hook_hashes_tl #1 ! \fi:
363     ?
364   \else:

```

(this `\use_i:nnnn` uses `\fi:` and consumes `\use:n`, the whole `\if_catcode:w` block, and the `\exp_not:N`, leaving just `#1` which is `\c__hook_hashes_tl`.)

```

365   \use_i:nnnn
366   \fi:
367   \use:n
368   {

```

If `#1` is not `\c__hook_hashes_tl`, then check if its catcode is 6, and if so, leave it doubled in `\exp_not:n` and consume the following `\exp_not:N #1`.

```

369   \if_catcode:w ## \exp_not:N #1
370   \exp_after:wN \use_ii:nnnn
371   \fi:
372   \use_none:n
373   { \exp_not:n { #1 #1 } }
374   }

```

If both previous tests returned false, then leave the token unexpanded and resume the loop.

```

375   \exp_not:N #1
376   \__hook_double_hashes:w
377   }
378 \cs_new:Npn \__hook_double_hashes_stop:w #1 \q__hook_recursion_stop { \fi: }

```

Dealing with spaces and grouped tokens is trivial:

```

379 \cs_new:Npn \__hook_double_hashes_group:n #1
380 { { \__hook_double_hashes:n {#1} } \__hook_double_hashes:w }
381 \exp_last_unbraced:NNo
382 \cs_new:Npn \__hook_double_hashes_space:w \c_space_tl
383 { ~ \__hook_double_hashes:w }

```

(End of definition for `\__hook_double_hashes:n` and others.)

#### 4.5.2 Patching by retokenization

At this point we've drained the possibilities of patching a command by expansion-and-redefinition, so we have to resort to patching by retokenizing the command. Patching by retokenization is done by getting the `\meaning` of the command, doing the necessary manipulations on the generated string, and the retokenizing that again by using `\scantokens`.

Patching by retokenization is definitely a riskier business, because it relies that the tokens printed by `\meaning` produce the exact same tokens as the ones in the original

definition. That is, the catcode régime must be exactly(ish) the same, and there is no way of telling except by trial and error.

`\__hook_retokenize_patch:Nnn` This is the macro that will control the whole process. First we'll try out one final, rather trivial case, of a command with no arguments; that is, a token list. This case can be patched with the expand-and-redefine routine but it has to be the very last case tested for, because most (all?) robust commands start with a top-level macro with no arguments, so testing this first would short-circuit `\robust@command@act` and the top-level macros would be incorrectly patched. In that case, we just check if the `\cs_parameter_spec:N` is empty, and call `\__hook_patch_expand_redefine:NNnn`.

```

384 \cs_new_protected:Npn \__hook_retokenize_patch:Nnn #1 #2 #3
385 {
386   \str_if_eq:eeTF { \__kernel_cs_parameter_spec:N #1 } { }
387   { \__hook_patch_expand_redefine:NNnn \c_false_bool #1 {#2} {#3} }
388   {
389     \__hook_patch_debug:x { ..~command~can~only~be~patched~by~rescanning }

```

Otherwise, we start the actual patching by retokenization job. The code calls `\__hook_try_patch_with_catcodes:Nnnnw` with a different catcode setting:

- The current catcode setting;
- Switching the catcode of `@`;
- Switching the `expl3` syntax on or off;
- Both of the above.

If patching succeeds, `\__hook_try_patch_with_catcodes:Nnnnw` has the side-effect of patching the macro `#1` (which may be an internal from the command whose name is `#2`).

```

390   \tl_set:Nx \l__hook_tmpa_tl
391   {
392     \int_compare:nNnTF { \char_value_catcode:n {'\@ } } = { 12 }
393     { \exp_not:N \makeatletter } { \exp_not:N \makeatother }
394   }
395   \tl_set:Nx \l__hook_tmpb_tl
396   {
397     \bool_if:NTF \l__kernel_expl_bool
398     { \ExplSyntaxOff }
399     { \ExplSyntaxOn \char_set_catcode_space:n { 32 }}
400   }
401   \use:x
402   {
403     \exp_not:N \__hook_try_patch_with_catcodes:Nnnnw
404     \exp_not:n { #1 {#2} {#3} }
405     { \prg_do_nothing: }
406     { \exp_not:V \l__hook_tmpa_tl } % @
407     { \exp_not:V \l__hook_tmpb_tl } % _:
408     {
409       \exp_not:V \l__hook_tmpa_tl % @
410       \exp_not:V \l__hook_tmpb_tl % _:
411     }
412   }
413   \q_recursion_tail \q_recursion_stop

```

If no catcode setting succeeds, give up and raise an error. The command isn't changed in any way in that case.

```

414         {
415             \msg_error:nnxx { hooks } { cant-patch }
416             { \c_backslash_str #2 } { retok }
417         }
418     }
419 }

```

(End of definition for \\_\_hook\_retokenize\_patch:Nnn.)

\\_\_hook\_try\_patch\_with\_catcodes:Nnnnw

This function is a simple wrapper around \\_\_hook\_cmd\_if\_scanable:NnTF and \\_\_hook\_patch\_retokenize:Nnnn if the former returns `<true>`, plus some debug messages.

```

457 <latexrelease> \EndIncludeInRelease

```

(End of definition for \\_\_hook\_try\_patch\_with\_catcodes:Nnnnw.)

`\kerneltmpDoNotUse` This is an oddity required to be safe (as safe as reasonably possible) when patching the command. The entirety of

```
⟨prefixes⟩ \def ⟨cs⟩ ⟨parameter text⟩ {⟨replacement text⟩}
```

will go through `\scantokens`. The `⟨parameter text⟩` and `⟨replacement text⟩` are what we are trying to retokenize, so not much worry there. The other items, however, should “just work”, so some care is needed to not use too fancy catcode settings. Therefore we can’t use an `expl3`-named macro for `⟨cs⟩`, nor the `expl3` versions of `\def` or the `⟨prefixes⟩`. That is why the definitions that will eventually go into `\scantokens` will use the oddly (but hopefully clearly)-named `\kerneltmpDoNotUse`:

```
458 \cs_new_eq:NN \kerneltmpDoNotUse !
```

*PhO: Maybe this can be avoided by running the `⟨parameter text⟩` and the `⟨replacement text⟩` separately through `\scantokens` and then putting everything together at the end.*

(End of definition for `\kerneltmpDoNotUse`.)

`\_hook_patch_required_catcodes:` Here are the catcode settings that are *mandatory* when retokenizing commands. These are the minimum necessary settings to perform the definitions: they identify control sequences, which must be escaped with `\_0`, delimit the definition with `{\_1` and `}\_2`, and mark parameters with `\_6`. Everything else may be changed, but not these.

```
459 \cs_new_protected:Npn \_hook_patch_required_catcodes:
460 {
461   \char_set_catcode_escape:N \_
462   \char_set_catcode_group_begin:N \_
463   \char_set_catcode_group_end:N \_
464   \char_set_catcode_parameter:N \_6
465   % \int_set:Nn \tex_endlinechar:D { -1 }
466   % \int_set:Nn \tex_newlinechar:D { -1 }
467 }
```

*PhO: etoolbox sets the `\endlinechar` and `\newlinechar` when patching, but as far as I tested these didn’t make much of a difference, so I left them out for now. Maybe `\newlinechar=-1` avoids a space token being added after the definition.*

*PhO: If the patching is split by `⟨parameter text⟩` and `⟨replacement text⟩`, then only `\_#` will have to stay in that list.*

*PhO: Actually now that we patch `\UseHook{cmd/foo/before}`, all the tokens there need to have the right catcodes, so this list now includes all lowercase letters, *U* and *H*, the slash, and whatever characters in the command name... sigh...*

(End of definition for `\_hook_patch_required_catcodes:`.)

`\_hook_cmd_if_scanable:NnTF` Here we’ll do a quick test if the command being patched can in fact be retokenized with the specific catcode setting without changing in meaning. The test is straightforward:

1. apply `\meaning` to the command;
2. split the `⟨prefixes⟩`, `⟨parameter text⟩` and `⟨replacement text⟩` and arrange them as

```
⟨prefixes⟩ \def \kerneltmpDoNotUse ⟨parameter text⟩ {⟨replacement text⟩}
```

3. rescan that with the given catcode settings, and do the definition; then finally

4. compare \kerneltmpDoNotUse with the original command.

If both are \ifx-equal, the command can be safely patched.

```

468 \prg_new_protected_conditional:Npnn \__hook_cmd_if_scanable:Nn #1 #2 { TF }
469 {
470   \cs_set_eq:NN \kerneltmpDoNotUse \scan_stop:

499     \c_hash_str 0 \s__hook_mark
500   }
501 }
502 \use:e
503 { \cs_new:Npn \exp_not:N \__hook_guess_arg_count:nw #1 #2 \c_hash_str #3 }
504 {
505   \int_compare:nNnTF { #1 + 1 } = {#3}
506     { \__hook_guess_arg_count:nw {#3} }
507     { #1 \__hook_use_none_delimit_by_s_mark:w }
508 }
509 <latexrelease>\EndIncludeInRelease
510 <latexrelease>\IncludeInRelease{2021/06/01}{\__hook_guess_arg_count:NN}
511 <latexrelease> {cmd~hooks~with~args}

```

512 `\(latexrelease)\cs_undefine:N \_\hook_guess_arg_count:NN`

513 `\(latexrelease)\EndIncludeInRelease`

(End of definition for `\_\hook_guess_arg_count:NN`, `\_\hook_guess_arg_count:wN`, and `\_\hook_guess_arg_count:nw`.)

`\_\hook_patch_retokenize:Nnnn`

Then, if `\_\hook_cmd_if_scanable:NnTF` returned true, we can go on and patch the command.

514 `\(latexrelease)\IncludeInRelease{2023/06/01}{\_\hook_patch_retokenize:Nnnn}`

515 `\(latexrelease)\cmd-hooks-with-args}`

516 `\cs_new_protected:Npn \_\hook_patch_retokenize:Nnnn #1 #2 #3 #4`

517 `{`

Here, when patching by retokenization, we can only guess the number of arguments of the macro.

518 `\_\hook_guess_arg_count:NN #1 \l_\hook_patch_num_args_int`

Then we redefine the hook to have the right number of arguments. Disabling the hook, undefining the `parameter` token list then calling `\_\hook_make_usable:nn` are enough to redefine the hook to the extent we want. Code stored in the hook and other metadata about it are not lost in the process.

519 `\_\hook_disable:n {#2}`

520 `\cs_undefine:c { c_\hook_#2_parameter_tl }`

521 `\_\hook_make_usable:nn {#2} { \l_\hook_patch_num_args_int }`

522 `\tl_set:Ne \l_\hook_tmpa_tl`

523 `{ \exp_args:Ne \tl_to_str:n { \_\hook_braced_parameter:n {#2} } }`

524 `\use:x`

525 `{`

526 `\str_replace_all:Nnn \exp_not:N \l_\hook_tmpa_tl`

527 `{ #### } { \c_hash_str }`

528 `}`

Then, make some things `\relax` to avoid lots of `\noexpand` below.

529 `\cs_set_eq:NN \kerneltmpDoNotUse \scan_stop:`

530 `\cs_set_eq:NN \_\hook_tmp:w \scan_stop:`

531 `\use:x`

532 `{`

Now we'll define `\_\hook_tmp:w` such that it splits the `\meaning` of the macro (`#1`) into its three parts:

####1. *<prefixes>*

####2. *<parameter text>*

####3. *<replacement text>*

and arrange that a complete definition, then place the `before` or `after` hooks around the *<replacement text>*: accordingly.

533 `\cs_set:Npn \_\hook_tmp:w`

534 `####1 \tl_to_str:n { macro: } ####2 -> ####3 \s_\hook_mark`

535 `{`

536 `####1 \def \kerneltmpDoNotUse ####2`

537 `{`

538 `\str_if_eq:nnT {#3} { before }`

539 `{`

```

540         \token_to_str:N \UseHookWithArguments {#2}
541         { \int_use:N \l__hook_patch_num_args_int }
542         \l__hook_tmpa_tl
543     }
544     ####3
545     \str_if_eq:nnT {#3} { after }
546     {
547         \token_to_str:N \UseHookWithArguments {#2}
548         { \int_use:N \l__hook_patch_num_args_int }
549         \l__hook_tmpa_tl
550     }
551 }
552 }

```

Now we just have to get the `\meaning` of the command being patched and pass it through the meat grinder above.

```

553     \tl_set:Nx \exp_not:N \l__hook_tmpa_tl
554     { \exp_not:N \__hook_tmp:w \token_to_meaning:N #1 \s__hook_mark }
555 }

```

Now rescan with the given catcode settings (overridden by the `\__hook_patch_required_catcodes:`), and implicitly (by using the rescanned token list) carry out the definition from above.

```

556     \tl_rescan:nV { #4 \__hook_patch_required_catcodes: } \l__hook_tmpa_tl

```

And to close, copy the newly-defined command into the old name and the patching is finally completed:

```

557     \cs_gset_eq:NN #1 \kerneltmpDoNotUse

```

Finally, update the hook code.

```

558     \__hook_update_hook_code:n {#2}
559 }
560 <latexrelease> \EndIncludeInRelease

## ltsockets.dtx

### Abstract

This code implements sockets which are places in the code into which predeclared chunks of code (plugs) can be placed. Both the sockets and the plugs are “named” and each socket is assigned exactly one plug at any given time.

## 1 Introduction

A L<sup>A</sup>T<sub>E</sub>X source file is transformed into a typeset document by executing code for each command or environment in the document source. Through various steps this code transforms the input and eventually generates typeset output appearing in a “galley” from which individual pages are cut off in an asynchronous way. This page generating process is normally not directly associated with commands in the input<sup>21</sup> but is triggered whenever the galley has received enough material to form another page (giving current settings).

As part of this transformation input data may get stored in some form and later reused, for example, as part of the output routine processing.

## 2 Configuration of the transformation process

There are three different major methods offered by L<sup>A</sup>T<sub>E</sub>X to configure the transformation process:

- through the template mechanism,
- through the hook mechanism, or
- through sockets and plugs.

They offer different possibilities (with different features and limitations) and are intended for specific use cases, though it is possible to combine them.

### 2.1 The template mechanism

The template mechanism is intended for more complex document-level elements (e.g., headings such as `\section` or environments like `itemize`). The template code implements the overall processing logic for such an element and offers a set of parameters to influence the final result.

The document element is then implemented by (a) selecting a suitable template (there may be more than one available for the kind of document element) and (b) by setting its parameters to desired values. This then forms a so-called instance which is executed when the document element is found in the source.

By altering the parameter values (in a document class or in the document preamble) or, if more drastic layout changes are desired, by selecting a different template and

---

<sup>21</sup>Excepts for directives such as `\newpage`.

then adjusting its parameters, a wide variety of layouts can be realized through simple configuration setups without the need to develop new code.

The target audience of this method are therefore document class developers or users who wish to alter an existing layout (implemented by a document class) in certain (minor) ways.

The template mechanism is currently documented as part of the `xtemplate` package and one more elaborate implementation can be found as part of the `latex-lab` code for lists (to be documented further).

## 2.2 The hook mechanism

Hooks are places in the kernel code (or in packages) that offer packages the possibility to inject additional code at specific points in the processing in a controlled way without the need to replace the existing code block (and thereby overwriting modifications/extensions made by other packages). The target audience is therefore mainly package developers, even though some hooks can be useful for document authors.

Obviously, what can reasonably be added into a hook depends on the individual hook (hopefully documented as part of the hook documentation), but in general the idea behind hooks is that more than one package could add code into the hook at the same time. Perhaps the most famous hook (that L<sup>A</sup>T<sub>E</sub>X had for a very long time) is `begindocument` into which many packages add code to through `\AtBeginDocument{<code>}` (which is nowadays implemented as a shorthand for `\AddToHook{begindocument}{<code>}`). To resolve possible conflicts between injections by different packages there is a rule mechanism by which code chunks in a hook can be ordered in a certain way and by which incompatible packages can be detected if a resolution is impossible.

In contrast to template code, there is no standard configuration method through parameters for hooks, i.e., the code added to a hook “is” the configuration. If it wants to provide for configuration through parameters it has to also provide its own method to set such parameters in some way. However, in that case it is likely that using a hook is not the right approach and the developer better calls a template instance instead which then offers configuration through a key/value interface.

In most cases, hooks do not take any arguments as input. Instead, the data that they can (and are allowed to) access depends on the surrounding context.

For example, the various hooks available during the page shipout process in L<sup>A</sup>T<sub>E</sub>X’s output routine can (and have to) access the accumulated page material stored in a box named `\ShipoutBox`. This way, code added to, say, the `shipout/before` hook could access the page content, alter it, and then write it back into `\ShipoutBox` and any other code added to this hook could then operate on the modified content. Of course, for such a scheme to work the code prior to executing the hook would need to setup up data in appropriate places and the hook documentation would need to document what kind of storage can be accessed (and possibly altered) by the hook.

There are also hooks that take arguments (typically portions of document data) and in that case the hook code can access these arguments through `#1`, `#2`, etc.

The hook mechanism is documented in `lthooks-doc.pdf`.

## 2.3 The socket mechanism

In some cases there is code that implements a certain programming logic (for example, combining footnotes, floats, and the text for the current page to be shipped out) and

if this logic should change (e.g., footnotes to be placed above bottom floats instead of below) then this whole code block needs to be replaced with different code.

In theory, this could be implemented with templates, i.e., the code simply calls some instance that implements the logic and that instance is altered by selecting a different templates and/or adjusting their parameters. However, in many cases customization through parameters is overkill in such a case (or otherwise awkward, because parameterization is better done on a higher level instead of individually for small blocks of code) and using the template mechanism just to replace one block of code with a different one results in a fairly high performance hit. It is therefore usually not a good choice.

In theory, it would also be possible to use a hook, but again that is basically a misuse of the concept, because in this use case there should never be more than one block of code inside the hook; thus, to alter the processing logic one would need to set up rules that replace code rather than (as intended) execute all code added to the hook.

For this reason L<sup>A</sup>T<sub>E</sub>X now offers a third mechanism: “sockets” into which one can place exactly one code block — a “plug”.

In a nutshell: instead of having a fixed code block somewhere as part of the code, implementing a certain programming logic there is a reference to a named socket at this point. This is done by first declaring the named socket with:

```
\NewSocket{<socket-name>}{<number-of-inputs>}
```

This is then referenced at the point where the replaceable code block should be executed with:

```
\UseSocket{<socket-name>}
```

or, if the socket should take a number of inputs (additional arguments beside the name) with

```
\UseSocket{<socket-name>}{<arg1>}...{<argnumber-of-inputs>}}
```

In addition, several code blocks (a.k.a. plugs) implementing different logic for this socket are set up, each with a declaration of the form:

```
\NewSocketPlug{<socket-name>}{<socket-plug-name>}{<code>}
```

Finally, one of them is assigned to the socket:

```
\AssignSocketPlug{<socket-name>}{<socket-plug-name>}
```

If the programming logic should change, then all that is necessary is to make a new assignment with `\AssignSocketPlug` to a different `{<socket-plug-name>}`. This assignment obeys scope so that an environment can alter a socket without the need to restore the previous setting manually.

If the socket takes inputs, then those need to be provided to `\UseSocket` and in that case they can be referenced in the `<code>` argument of `\NewSocketPlug` with `#1`, `#2`, etc.

In most cases a named socket is used only in a single place, but there is, of course, nothing wrong with using it in several places, as long as the code in all places is supposed to change in the same way.

### 2.3.1 Examples

We start by declaring a new socket named `foo` that expects two inputs:

```
\NewSocket{foo}{2}
```

Such a declaration has to be unique across the whole L<sup>A</sup>T<sub>E</sub>X run. Thus, if another package attempts to use the same name (regardless of the number of inputs) it will generate an error:

```
\NewSocket{foo}{2}
\NewSocket{foo}{1}
```

Both declarations would therefore produce:

```
! LaTeX socket Error: Socket 'foo' already declared!
```

You also get an error if you attempt to declare some socket plug and the socket name is not yet declared, e.g.,

```
\NewSocketPlug{baz}{undeclared}{some code}
```

generates

```
! LaTeX socket Error: Socket 'baz' undeclared!
```

Setting up plugs for the socket is done like this:

```
\NewSocketPlug{foo}{plug-A}
  {\begin{quote}\itshape foo-A: #1!#2\end{quote}}
\NewSocketPlug{foo}{plug-B}
  {\begin{quote}\sffamily foo-B: #2\textsuperscript{2}\end{quote}}
```

This will set up the plugs `plug-A` and `plug-B` for this socket.

We still have to assign one or the other to the socket, thus without doing that the line

```
\UseSocket{foo}{hello}{world}
```

produces nothing because the default plug for sockets with 2 inputs is `noop` (which grabs the additional arguments and throws them away).<sup>22</sup>

So let's do the assignment

```
\AssignSocketPlug{foo}{plug-A}
```

and then

```
\UseSocket{foo}{hello}{world}
```

will properly typeset

*foo-A: hello!world*

and after

```
\AssignSocketPlug{foo}{plug-B}
```

---

<sup>22</sup>If socket `foo` would have been a socket with one input, then the default plug would be `identity`, in which case the socket input would remain without braces and gets typeset!

and another call to

```
\UseSocket{foo}{hello}{world}
```

we get

```
foo-B: world2
```

If we attempt to assign a plug that was not defined, e.g.,

```
\AssignSocketPlug{foo}{plug-C}
```

then we get an error during the assignment

```
! LaTeX socket Error: Plug 'plug-C' for socket 'foo' undeclared!
```

and the previous assignment remains in place.

To see what is known about a socket and its plugs you can use `\ShowSocket` or `\LogSocket` which displays information similar to this on the terminal or in the transcript file:

```
Socket foo:
  number of inputs = 2
  available plugs = noop, plug-A, plug-B
  current plug = plug-B
  definition = \long macro:#1#2->\begin {quote}\sffamily
foo-B: #2\textsuperscript {2}\end {quote}
```

### 2.3.2 Details and semantics

In this section we collect some normative statements.

- From a functional point of view sockets are like simple `TeX` macros, i.e., they expect 0 to 9 mandatory arguments (the socket inputs) and get replaced by their “expansion”
- A socket is “named” and the name consists of ASCII letters `[a-z]`, `[A-Z]`, `[0-9]`, `[-/@]` only
- Socket names have to be unique, i.e., there can be only one socket named `<name>`. This is ensured by declaring each socket with `\NewSocket`.

However, there is no requirement that sockets and hook names have to be different. In fact, if a certain action that could otherwise be specified as hook code has to be executed always last (or first) one could ensure this by placing a socket (single action) after a hook (or vice versa) and using the same name to indicate the relationship, e.g.,

```
\UseHook{foo}          % different package can add code here
\UseSocket{foo}         % only one package can assign a plug
```

This avoids the need to order the hook code to ensure that something is always last.

- Best practice naming conventions are ... *to be documented*

- A socket has documented inputs which are
  - the positional arguments (if any) with a description of what they contain when used
  - implicit data (registers and other 2e/expl3 data stores) that the socket is allowed to make use of, with a documented description of what they contain (if relevant for the task at hand—no need to describe the whole L<sup>A</sup>T<sub>E</sub>X universe)
  - information about the state of the T<sub>E</sub>X engine (again when relevant), e.g. is called in mmode or vmode or in the output routine or ...
  - ... anything missing?
- A socket has documented results/outputs which can be
  - what kind of data it should write to the current list (if that is part of its task)
  - what kind of registers and other 2e/expl3 data stores it should modify and in what way
  - what kind of state changes it should do (if any)
  - ... *anything else*?
- At any time a socket has one block of code (a plug :-)) associated with it. Such code is itself named and the association is done by linking the socket name to the code name (putting a plug into the socket).
- The name of a plug consists of ASCII letters [a-z], [A-Z], [0-9], [-/@] only.
- Socket plug names have to be unique within on a per socket basis, but it is perfectly allowed (and sensible in some cases) to use the same plug name with different sockets (where based on the sockets' purposes, different actions may be associated with the plug name). For example `noop` is a plug name declared for every socket, yet its action “grab the socket inputs and throw them away” obviously differs depending on how many inputs the socket has.
- When declaring a plug it is stated for which socket it is meant (i.e., its code can only be used with that socket). This means that the same plug name can be used with different sockets referring to different code in each case.
- Configuration of a socket can only be done by linking different code to it. Nevertheless the code linked to it can provide its own means of configuration (but this is outside of the spec).
- Technically execution of a socket (`\UseSocket`) involves
  - doing any house keeping (like writing debugging info, ...);
  - looking up the current code association (what plug is in the socket);
  - executing this code which will pick up the mandatory arguments (happens at this point, not before), i.e., it is like calling a csname defined with
 

```
\def\foo#1#2...{\...#1...#2...}
```
  - do some further house keeping (if needed).
- A socket is typically only used in one place in code, but this is not a requirement, i.e., if the same operation with the same inputs need to be carried out in several places the same named socket can be used.

### 2.3.3 Command syntax

We give both the L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> and the L3 programming layer command names.

---

<code>\NewSocket</code>	<code>\NewSocket</code>	<code>{\socket-name}</code>	<code>{\number-of-inputs}</code>
<code>\socket_new:nn</code>	<code>\socket_new:nn</code>	<code>{\socket-name}</code>	<code>{\number-of-inputs}</code>

---

Declares a new socket with name `\socket-name` having `\number-of-inputs` inputs. There is automatically a plug `noop` declared for it, which does nothing, i.e., it gobbles the socket inputs (if any). This is made the default plug except for sockets with one input which additionally define the plug `identity` and assign that as their default.

This `identity` plug simply returns the socket input without its outer braces. The use case for this plug are situations like this:

`\UseSocket{taggsupport/footnote}{\code}`

If tagging is not active and the socket contains the plug `identity` then this returns `\code` without the outer braces and to activate tagging all that is necessary is to change the plug to say `tagpdf` so that it surrounds `\code` by some tagging magic. This is the most common use case for sockets with one input, which is why they have this special default.

The socket documentation should describe its purpose, its inputs and the expected results as discussed above.

The declaration is only allowed at top-level, i.e., not inside a group.

---

<code>\NewSocketPlug</code>	<code>\NewSocketPlug</code>	<code>{\socket-name}</code>	<code>{\socket-plug-name}</code>	<code>{\code}</code>
<code>\socket_new_plug:nnn</code>	<code>\socket_new_plug:nnn</code>	<code>{\socket-name}</code>	<code>{\socket-plug-name}</code>	<code>{\code}</code>
<code>\socket_set_plug:nnn</code>	<code>\socket_set_plug:nnn</code>	<code>{\socket-name}</code>	<code>{\socket-plug-name}</code>	<code>{\code}</code>

---

Declares a new plug for socket `\socket-name` that runs `\code` when executing. It complains if the plug was already declared previously.

The form `\socket_set_plug:nnn` changes an existing plug. As this should normally not be necessary, we currently have only an L3 layer name for the few cases it might be useful.

The declarations can be made inside a group and obey scope, i.e., they vanish if the group ends.

---

<code>\AssignSocketPlug</code>	<code>\AssignSocketPlug</code>	<code>{\socket-name}</code>	<code>{\socket-plug-name}</code>
<code>\socket_assign_plug:nn</code>	<code>\socket_assign_plug:nn</code>	<code>{\socket-name}</code>	<code>{\socket-plug-name}</code>

---

Assigns the plug `\socket-plug-name` to the socket `\socket-name`. It errors if either socket or plug is not defined.

The assignment is local, i.e., it obeys scope.

<hr/>	<hr/>
<code>\UseSocket</code>	<code>\UseSocket        {&lt;socket-name&gt;}</code>
<code>\socket_use:nw</code>	<code>\socket_use:nnn {&lt;socket-name&gt;} {&lt;socket-arg<sub>1</sub>&gt;} {&lt;socket-arg<sub>2</sub>&gt;}</code>
<code>\socket_use:n</code>	Executes the socket <code>&lt;socket-name&gt;</code> by retrieving the <code>&lt;code&gt;</code> of the current plug assigned to the socket. This is the only command that would appear inside macro code in packages.
<code>\socket_use:nn</code>	For performance reasons there is no explicit check that the socket was declared!
<code>\socket_use:nnn</code>	The different L3 programming layer commands are really doing the same thing: they grab as many arguments as defined as inputs for the socket and then pass them to the plug. The different names are only there to make the code more readable, i.e., to indicate how many arguments are grabbed in total (note that no runtime check is made to verify that this is actually true). We only provide them for sockets with up to 3 inputs (most likely those with zero or one input would have been sufficient). If you happen to have a socket with more inputs, use <code>\socket_use:nw</code> .
<code>\socket_use:nnnn</code>	

<hr/>	<hr/>
<code>\socket_use_expandable:nw</code>	<code>* \socket_use_expandable:n {&lt;socket-name&gt;}</code>
<code>\socket_use_expandable:n</code>	<code>*</code>

Fully expandable variant of `\socket_use:n`. This can be used in macro code to retrieve code from sockets which need to appear in an expandable context.

This usually requires the plug to only contain expandable code and should therefore only be used for sockets which are clearly documented to be used in an expandable context. This command does not print any debugging info when `\DebugSocketsOn` is active and should therefore be avoided whenever possible.

For performance reasons there is no explicit check that the socket was declared!

<hr/>	<hr/>
<code>\ShowSocket</code>	<code>\ShowSocket    {&lt;socket-name&gt;}</code>
<code>\LogSocket</code>	<code>\socket_show:n {&lt;socket-name&gt;}</code>
<code>\socket_show:n</code>	Displays information about the socket <code>&lt;socket-name&gt;</code> and its state then stops and waits for further instructions — at the moment some what rudimentary.
<code>\socket_log:n</code>	<code>\LogSocket</code> and <code>\socket_log:n</code> only differ in that they don't stop.

It is sometimes necessary/helpful to know if a particular socket or plug exists (or is assigned to a certain socket) and based on that take different actions.

<hr/>	<hr/>
<code>\IfSocketExistsTF</code>	<code>* \IfSocketExistsTF {&lt;socket-name&gt;} {&lt;true code&gt;} {&lt;false code&gt;}</code>
<code>\socket_if_exist:nTF</code>	<code>*</code> If socket <code>&lt;socket-name&gt;</code> exists then execute <code>&lt;true code&gt;</code> otherwise <code>&lt;false code&gt;</code> . Variants with only T or F are also available.

<hr/>	<hr/>
<code>\IfSocketPlugExistsTF</code>	<code>* \IfSocketPlugExistsTF {&lt;socket-name&gt;} {&lt;plug-name&gt;}</code>
<code>\socket_if_plug_exist:nnTF</code>	<code>*        {&lt;true code&gt;} {&lt;false code&gt;}</code>
	If plug <code>&lt;plug-name&gt;</code> for socket <code>&lt;socket-name&gt;</code> exists then execute <code>&lt;true code&gt;</code> otherwise <code>&lt;false code&gt;</code> . Variants with only T or F are also available.

<hr/>	<hr/>
<code>\IfSocketPlugAssignedTF</code>	<code>* \IfSocketPlugAssignedTF {&lt;socket-name&gt;} {&lt;plug-name&gt;}</code>
<code>\socket_if_plug_assigned:nnTF</code>	<code>*        {&lt;true code&gt;} {&lt;false code&gt;}</code>

If plug `<plug-name>` is assigned to socket `<socket-name>` then execute `<true code>` otherwise `<false code>`. Variants with only T or F are also available.

---

<code>\DebugSocketsOn</code>	<code>\DebugSocketsOn ... \DebugSocketsOff</code>
<code>\DebugSocketsOff</code>	Turns debugging of sockets on or off.
<code>\socket_debug_on:</code>	
<code>\socket_debug_off:</code>	

---

### 2.3.4 Rationale for error handling

The errors during the declarations are produced to help with typos—after all, such declarations might be part of a document preamble (not that likely, but possible). However, `\UseSocket` is not doing much checking, e.g.,

```
\UseSocket{mispelled-socket}{hello}{world}
```

will generate a rather low-level error and then typesets “helloworld” because there is no dedicated runtime check if `mispelled-socket` is a known socket.

The reason is that if the misspelling is in the code, then this is a programming error in the package and for speed reasons L<sup>A</sup>T<sub>E</sub>X does not repeatedly make runtime checks for coding errors unless they can or are likely to be user introduced.

## 3 The Implementation

The implementation of the socket mechanism should be (partially) redone and we should probably store the different code chunks in a property list so that we can have a decent `\ShowSocket` command that shows the available alternatives.

TODO: *implement?*

```

1 <*2ekernel | latexrelease>
2 \ExplSyntaxOn
3 <@@=socket>
4 <latexrelease> \NewModuleRelease{2023/11/01}{ltsockets}
5 <latexrelease> {The~socket~management~system}
```

### 3.1 Debugging the socket structures

Code and commands in this section are not final, it needs more experimentation to see what kind of tracing information is going to be useful in practice. For now the tracing is mainly meant to be used for code testing and not so much for application testing.

It is quite likely that the commands and the behavior of the tracing might change in the future once we gained some experience with it.

<code>\g__socket_debug_bool</code>	Holds the current debugging state.
<code>\bool_new:N \g__socket_debug_bool</code>	
<i>(End of definition for \g__socket_debug_bool.)</i>	
<code>\socket_debug_on:</code>	Turns debugging on and off by redefining <code>\__socket_debug:n</code> and <code>\__socket_debug_term:n</code> . By default they do nothing.
<code>\socket_debug_off:</code>	
<code>\__socket_debug:n</code>	<code>\cs_new_eq:NN \__socket_debug:n \use_none:n</code>
<code>\__socket_debug_term:n</code>	<code>\cs_new_eq:NN \__socket_debug_term:n \use_none:n</code>
<code>\__socket_debug_gset:</code>	

```

9 \cs_new_protected:Npn \socket_debug_on:
10 {
11   \bool_gset_true:N \g__socket_debug_bool
12   \__socket_debug_gset:
13 }
14 \cs_new_protected:Npn \socket_debug_off:
15 {
16   \bool_gset_false:N \g__socket_debug_bool
17   \__socket_debug_gset:
18 }
19 \cs_new_protected:Npn \__socket_debug_gset:
20 {
21   \cs_gset_protected:Npx \__socket_debug:n ##1
22   { \bool_if:NT \g__socket_debug_bool {##1} }
23   \cs_gset_protected:Npx \__socket_debug_term:n ##1
24   { \bool_if:NT \g__socket_debug_bool
25     { \iow_term:x { ^^J [Sockets]~ ==>~ ##1} } }
26 }

```

(End of definition for `\socket_debug_on:` and others. These functions are documented on page 345.)

### 3.2 The L3 layer commands

`\socket_new:nn` Declaring a socket creates a str to hold the name (a pointer) to the code that should be used when the socket is executed, and an integer to hold the number of inputs of that socket. Initially, an “empty” code chunk is created and assigned so the socket does nothing by default other than swallowing its inputs (if any).

```

27 \cs_new_protected:Npn \socket_new:nn #1 #2 {
28   \socket_if_exist:nTF {#1}
29   {
30     \msg_error:nnn { socket } { already-declared } {#1}
31   }
32   {

```

We only support declarations on top-level.

```

33   \int_if_zero:nTF \tex_currentgrouplevel:D
34   {
35     \str_new:c { l__socket_#1_plug_str }
36     \seq_new:c { l__socket_#1_plugs_seq }
37     \int_const:cn { c__socket_#1_args_int } {#2}
38     \socket_new_plug:nnn {#1} { noop } {}
39     \int_compare:nNnTF {#2} = 1
40     {
41       \socket_new_plug:nnn {#1} { identity } {##1}
42       \socket_assign_plug:nn {#1} { identity }
43     }
44     { \socket_assign_plug:nn {#1} { noop } }
45     \__socket_debug_term:n
46     { Socket~ '##1'~ declared~ with~ #2~ input(s) }
47   }
48   {
49     \msg_error:nn { socket } { not-top-level }
50   }
51 }

```

```
52 }
```

(End of definition for `\socket_new:nn`. This function is documented on page 343.)

`\socket_if_exist_p:n` Conditional testing the existence of a socket. The argument is fully expanded as part of the csname generation.

`\socket_if_exist:nTF`

```
53 \prg_new_conditional:Npnn \socket_if_exist:n #1 { p , T , F , TF }
54 { \str_if_exist:cTF { l__socket_#1_plug_str }
55   \prg_return_true:
56   \prg_return_false:
57 }
```

(End of definition for `\socket_if_exist:nTF`. This function is documented on page 344.)

`\socket_log:n` Show the current state of the socket — for now this is just a quick draft and should be redone and extended.

`\socket_show:n`

```
58 \cs_new_protected:Npn \socket_log:n #1 {
59   \typeout{ Socket~ #1:}
60   \socket_if_exist:nTF {#1}
61   {
62     \typeout{ @spaces number~ of~ inputs~ =~
63               \int_use:c { c__socket_#1_args_int } }
64     \typeout{ @spaces available~plugs~ =~
65               \seq_use:cnnn { l__socket_#1_plugs_seq }{,~}{,~}{,~} }
66     \typeout{ @spaces current~ plug~ =~
67               \str_use:c { l__socket_#1_plug_str } }
68     \typeout{ @spaces definition~ =~
69               \cs_meaning:c
70               { __socket_#1_plug_ \str_use:c { l__socket_#1_plug_str } :w } }
71     \typeout{}
72   }
73 }
```

If we are showing a socket it is not an error if it doesn't exist.

```
74   \typeout { Socket~ is~ not~ declared! }
75 }
76 }
```

And here the version that stops:

```
77 \cs_new_protected:Npn \socket_show:n #1 {\socket_log:n {#1} \errmessage{}}
```

(End of definition for `\socket_log:n` and `\socket_show:n`. These functions are documented on page 344.)

`\socket_new_plug:nnn` Declaring a code for a socket is just making a definition, taking the number of arguments from the saved int.

`\socket_set_plug:nnn`

```
78 \cs_new_protected:Npn \socket_new_plug:nnn #1#2#3 {
79   \socket_if_exist:nTF {#1}
80   {
81     \socket_if_plug_exist:nnTF {#1} {#2}
82     {
83       \msg_error:nnnn { socket } { plug-already-declared } {#1} {#2}
84     }
85     {
86       \cs_generate_from_arg_count:cNnn
```

```

87         { __socket_#1_plug_#2:w }
88         \cs_new:Npn
89         { \int_use:c { c__socket_#1_args_int } }
90         {#3}

```

This is a new declaration so we add the name to a seq for the debugging info.

```

91         \seq_put_right:cn { l__socket_#1_plugs_seq } {#2}
92         \__socket_debug_term:n
93         { Plug~ '2'~ for~ socket~ '1'~ declared. }
94     }
95 }
96 { \msg_error:nnn { socket } { undeclared } {#1} }
97 }

```

Changing the plug of an existing socket is rather similar, except that we don't have to deal with adding it to the debugging sequence.

```

98 \cs_new_protected:Npn \socket_set_plug:nnn #1#2#3 {
99     \socket_if_exist:nTF {#1}
100     {
101         \socket_if_plug_exist:nnTF {#1} {#2}
102         {
103             \cs_generate_from_arg_count:cNnn
104             { __socket_#1_plug_#2:w }
105             \cs_set:Npn
106             { \int_use:c { c__socket_#1_args_int } }
107             {#3}
108             \__socket_debug_term:n
109             { Plug~ '2'~ for~ socket~ '1'~ changed. }
110         }
111         {
112             \msg_error:nnnn { socket } { plug-undeclared } {#1} {#2}
113         }
114     }
115     { \msg_error:nnn { socket } { undeclared } {#1} }
116 }

```

*(End of definition for \socket\_new\_plug:nnn and \socket\_set\_plug:nnn. These functions are documented on page 343.)*

`\socket_if_plug_exist_p:nn` Conditional testing the existence of a plug. Both arguments are fully expanded as part of the csname generation.

`\socket_if_plug_exist:nnTF`

```

117 \prg_new_conditional:Npnn \socket_if_plug_exist:nn #1#2 { p , T , F , TF }
118 { \cs_if_exist:cTF { __socket_#1_plug_#2:w }
119     \prg_return_true:
120     \prg_return_false:
121 }

```

*(End of definition for \socket\_if\_plug\_exist:nnTF. This function is documented on page 344.)*

`\socket_assign_plug:nn` Assigning a plug to a socket just changes the name in the socket string. The assignment is local to the current group.

```

122 \cs_new_protected:Npn \socket_assign_plug:nn #1 #2 {
123     \socket_if_exist:nTF {#1}
124     {
125         \socket_if_plug_exist:nnTF {#1} {#2}

```

```

126     {
127         \__socket_debug_term:n
128         { Replacing~ plug~ '\str_use:c { l__socket_#1_plug_str }'~
129           with~ '#2'~ in~ socket~ '#1'. }
130         \str_set:cn { l__socket_#1_plug_str } {#2}
131     }
132     {
133         \msg_error:nnnn { socket } { plug-undeclared } {#1} {#2}
134     }
135 }
136 { \msg_error:nnn { socket } { undeclared } {#1} }
137 }

```

(End of definition for `\socket_assign_plug:nn`. This function is documented on page 343.)

```

\socket_if_plug_assigned_p:nn Conditional testing the assignment of a plug. Both arguments are fully expanded.
\socket_if_plug_assigned:nnTF
138 \prg_new_conditional:Npnn \socket_if_plug_assigned:nn #1#2 { p , T , F , TF }
139   { \exp_args:Ne
140     \str_if_eq:nvTF {#2} { l__socket_#1_plug_str }
141       \prg_return_true:
142       \prg_return_false:
143   }

```

(End of definition for `\socket_if_plug_assigned:nnTF`. This function is documented on page 344.)

`\socket_use:nw` And using it is more or less a `\use:c` so very lightweight. We do not add a runtime check for speed reasons!

`\socket_use:n` This command is named `\socket_use:nw` because we don't know how many inputs the socket has until we have looked at the socket name (in argument #1). But, of course,

`\socket_use:nn` the developer knows so we also offer a few aliases `\socket_use:nn`, etc. so that one can indicate the correct number of arguments (socket inputs plus one) in the L3 layer code.

`\socket_use:nnnn`

```

144 \cs_new_protected:Npn \socket_use:nw #1 {
145   \__socket_debug_term:n
146   { Socket~ '#1'~ containing~ plug~
147     '\str_use:c { l__socket_#1_plug_str }'~ used. }
148   \use:c { __socket_#1_plug_ \str_use:c { l__socket_#1_plug_str } :w }
149 }

```

To make code a bit more readable we also define functions that indicate how many arguments are picked up. However, this is just for code documentation: internally they all do the same and the number of arguments isn't checked by default.

```

150 \cs_new_eq:NN \socket_use:n \socket_use:nw % socket with no inputs
151 \cs_new_eq:NN \socket_use:nn \socket_use:nw % socket with one input
152 \cs_new_eq:NN \socket_use:nnn \socket_use:nw % socket with two inputs
153 \cs_new_eq:NN \socket_use:nnnn \socket_use:nw % socket with three inputs

```

The above commands could be changed to check how many inputs the socket is declared with (for example, when checking is in force).

TODO: Implement?

(End of definition for `\socket_use:nw` and others. These functions are documented on page 344.)

`\socket_use_expandable:nw`  
`\socket_use_expandable:n`

The same as the non-expandable code, except for the missing debug output.

```
154 \cs_new:Npn \socket_use_expandable:nw #1 {
155   \use:c { __socket_#1_plug_ \str_use:c { l__socket_#1_plug_str } :w }
156 }
157 \cs_new_eq:NN \socket_use_expandable:n \socket_use_expandable:nw % socket with no inputs
```

(End of definition for `\socket_use_expandable:nw` and `\socket_use_expandable:n`. These functions are documented on page 344.)

### 3.3 Error messages

```

## File 11

# lttemplates.dtx

## 1 Introduction

There are three broad “layers” between putting down ideas into a source file and ending up with a typeset document. These layers of document writing are

1. authoring of the text with mark-up;
2. document layout design;
3. implementation (with T<sub>E</sub>X programming) of the design.

We write the text as an author, and we see the visual output of the design after the document is generated; the T<sub>E</sub>X implementation in the middle is the glue between the two.

L<sup>A</sup>T<sub>E</sub>X’s greatest success has been to standardise a system of mark-up that balances the trade-off between ease of reading and ease of writing to suit almost all forms of technical writing. It’s other original strength was a good background in typographical design; while the standard L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> classes look somewhat dated now in terms of their visual design, their typography is generally sound (barring the occasional minor faults).

However, L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> has always lacked a standard approach to customising the visual design of a document. Changing the looks of the standard classes involved either:

- Creating a new version of the implementation code of the class and editing it.
- Loading one of the many packages to customise certain elements of the standard classes.
- Loading a completely different document class, such as KOMA-Script or memoir, that allows easy customization.

All three of these approaches have their drawbacks and learning curves.

The idea behind `lttemplates` is to cleanly separate the three layers introduced at the beginning of this section, so that document authors who are not programmers can easily change the design of their documents. `lttemplates` also makes it easier for L<sup>A</sup>T<sub>E</sub>X programmers to provide their own customizations on top of a pre-existing class.

## 2 What is a document?

Besides the textual content of the words themselves, the source file of a document contains mark-up elements that add structure to the document. These elements include sectional divisions, figure/table captions, lists of various sorts, theorems/proofs, and so on. The list will be different for every document that can be written.

Each element can be represented logically without worrying about the formatting, with mark-up such as `\section`, `\caption`, `\begin{enumerate}` and so on. The output of each one of these document elements will be a typeset representation of the information marked up, and the visual arrangement and design of these elements can vary widely in producing a variety of desired outcomes.

For each type of document element, there may be design variations that contain the same sort of information but present it in slightly different ways. For example, the difference between a numbered and an unnumbered section, `\section` and `\section*`, or the difference between an itemized list or an enumerated list.

There are three distinct layers in the definition of “a document” at this level

1. semantic elements such as the ideas of sections and lists;
2. a set of design solutions for representing these elements visually;
3. specific variations for these designs that represent the elements in the document.

In the parlance of the template system, these are called types, templates, and instances, and they are discussed below in sections 4, 5, and 7, respectively.

### 3 Types, templates, and instances

By formally declaring documents to be composed of mark-up elements grouped into types, which are interpreted and typeset with a set of templates, each of which has one or more instances with which to compose each and every semantic unit of the text, we can cleanly separate the components of document construction.

All of the structures provided by the template system are global, and do not respect  $\TeX$  grouping.

### 4 Template types

An *template type* (sometimes just “type”) is an abstract idea of a document element that takes a fixed number of arguments corresponding to the information from the document author that it is representing. A sectioning type, for example, might take three inputs: “title”, “short title”, and “label”.

Any given document class will define which types are to be used in the document, and any template of a given type can be used to generate an instance for the type. (Of course, different templates will produce different typeset representations, but the underlying content will be the same.)

---

```
\NewTemplateType <template type> {<no. of args>}
```

---

This function defines an `<template type>` taking `<number of arguments>`, where the `<type>` is an abstraction as discussed above. For example,

```
\NewTemplateType{sectioning}{3}
```

creates a type “sectioning”, where each use of that type will need three arguments.

### 5 Templates

A *template* is a generalized design solution for representing the information of a specified type. Templates that do the same thing, but in different ways, are grouped together by their type and given separate names. There are two important parts to a template:

- the parameters it takes to vary the design it is producing;

Key-type	Description of input
<code>boolean</code>	<code>true</code> or <code>false</code>
<code>choice{⟨choices⟩}</code>	A list of pre-defined <code>⟨choices⟩</code>
<code>commalist</code>	A comma-separated list
<code>function{⟨N⟩}</code>	A function definition with $N$ arguments ( $N$ from 0 to 9)
<code>instance{⟨name⟩}</code>	An instance of type <code>⟨name⟩</code>
<code>integer</code>	An integer or integer expression
<code>length</code>	A fixed length
<code>muskip</code>	A math length with shrink and stretch components
<code>real</code>	A real (floating point) value
<code>skip</code>	A length with shrink and stretch components
<code>tokenlist</code>	A token list: any text or commands

Table 1: Key-types for defining template interfaces with `\DeclareTemplateInterface`.

- the implementation of the design.

As a document author or designer does not care about the implementation but rather only the interface to the template, these two aspects of the template definition are split into two independent declarations, `\DeclareTemplateInterface` and `\DeclareTemplateCode`.

---

```

\DeclareTemplateInterface \DeclareTemplateInterface
  {⟨type⟩} {⟨template⟩} {⟨no. of args⟩}
  {⟨key list⟩}

```

---

A `⟨template⟩` interface is declared for a particular `⟨type⟩`, where the `⟨number of arguments⟩` must agree with the type declaration. The interface itself is defined by the `⟨key list⟩`, which is itself a key–value list taking a specialized format:

```

⟨key1⟩ ":" ⟨key type1⟩ ","
⟨key2⟩ ":" ⟨key type2⟩ ","
⟨key3⟩ ":" ⟨key type3⟩ "=" ⟨default3⟩ ","
⟨key4⟩ ":" ⟨key type4⟩ "=" ⟨default4⟩ ","
...

```

Each `⟨key⟩` name should consist of ASCII characters, with the exception of `,`, `=` and `:`. The recommended form for key names is to use lower case letters, with dashes to separate out different parts. Spaces are ignored in key names, so they can be included or missed out at will. Each `⟨key⟩` must have a `⟨key type⟩`, which defines the type of input that the `⟨key⟩` requires. A full list of key types is given in Table 1. Each key may have a `⟨default⟩` value, which will be used in by the template if the `⟨key⟩` is not set explicitly. The `⟨default⟩` should be of the correct form to be accepted by the `⟨key type⟩` of the `⟨key⟩`: this is not checked by the code. Expressions for numerical values are evaluated when the template is used, thus for example values given in terms of `em` or `ex` will be set respecting the prevailing font.

---

`\KeyValue` `\KeyValue {⟨key name⟩}`

---

There are occasions where the default (or value) for one key should be taken from another. The `\KeyValue` function can be used to transfer this information without needing to know the internal implementation of the key:

```
\DeclareTemplateInterface { type } { template } { no. of args }
{
  key-name-1 : key-type = value ,
  key-name-2 : key-type = \KeyValue { key-name-1 },
  ...
}
```

---

`\DeclareTemplateCode` `\DeclareTemplateCode`  
`{⟨type⟩} {⟨template⟩} {⟨no. of args⟩}`  
`{⟨key bindings⟩} {⟨code⟩}`

---

The relationship between a templates keys and the internal implementation is created using the `\DeclareTemplateCode` function. As with `\DeclareTemplateInterface`, the `⟨template⟩` name is given along with the `⟨type⟩` and `⟨number of arguments⟩` required. The `⟨key bindings⟩` argument is a key–value list which specifies the relationship between each `⟨key⟩` of the template interface with an underlying `⟨variable⟩`.

```
⟨key1⟩ "=" ⟨variable1⟩,
⟨key2⟩ "=" ⟨variable2⟩,
⟨key3⟩ "=" global ⟨variable3⟩,
⟨key4⟩ "=" global ⟨variable4⟩,
...
```

With the exception of the choice, code and function key types, the `⟨variable⟩` here should be the name of an existing L<sup>A</sup>T<sub>E</sub>X3 register. As illustrated, the key word “global” may be included in the listing to indicate that the `⟨variable⟩` should be assigned globally. A full list of variable bindings is given in Table 2.

The `⟨code⟩` argument of `\DeclareTemplateCode` is used as the replacement text for the template when it is used, either directly or as an instance. This may therefore accept arguments #1, #2, *etc.* as detailed by the `⟨number of arguments⟩` taken by the type.

---

`\AssignTemplateKeys` `\AssignTemplateKeys`

---

In the final argument of `\DeclareTemplateCode` the assignment of keys defined by the template may be delayed by including the command `\AssignTemplateKeys`. If this is *not* present, keys are assigned immediately before the template code. If an `\AssignTemplateKeys` command is present, assignment is delayed until this point. Note that the command must be *directly* present in the code, not placed within a nested command/macro.

Key-type	Description of binding
<code>boolean</code>	Boolean variable, <i>e.g.</i> <code>\l_tmpa_bool</code>
<code>choice</code>	List of choice implementations (see Section 6)
<code>commalist</code>	Comma list, <i>e.g.</i> <code>\l_tmpa_clist</code>
<code>function</code>	Function taking $N$ arguments, <i>e.g.</i> <code>\use_i:nn</code>
<code>instance</code>	
<code>integer</code>	Integer variable, <i>e.g.</i> <code>\l_tmpa_int</code>
<code>length</code>	Dimension variable, <i>e.g.</i> <code>\l_tmpa_dim</code>
<code>muskip</code>	Muskip variable, <i>e.g.</i> <code>\l_tmpa_muskip</code>
<code>real</code>	Floating-point variable, <i>e.g.</i> <code>\l_tmpa_fp</code>
<code>skip</code>	Skip variable, <i>e.g.</i> <code>\l_tmpa_skip</code>
<code>tokenlist</code>	Token list variable, <i>e.g.</i> <code>\l_tmpa_tl</code>

Table 2: Bindings required for different key types when defining template implementations with `\DeclareTemplateCode`. Apart from `code`, `choice` and `function` all of these accept the key word `global` to carry out a global assignment.

<code>\SetKnownTemplateKeys</code>	<code>\SetKnownTemplateKeys {&lt;type&gt;} {&lt;template&gt;} {&lt;keyvals&gt;}</code>
<code>\SetTemplateKeys</code>	<code>\SetTemplateKeys {&lt;type&gt;} {&lt;template&gt;} {&lt;keyvals&gt;}</code>
<code>\UnusedTemplateKeys</code>	<code>\UnusedTemplateKeys % all &lt;keyvals&gt; unused by previous \SetKnownTemplateKeys</code>

In the final argument of `\DeclareTemplateCode` one can also overwrite (some of) the current template key value settings by using the command `\SetKnownTemplateKeys` or `\SetTemplateKeys`, i.e., they can overwrite the template default values and the values assigned by the instance.

The `\SetKnownTemplateKeys` and `\SetTemplateKeys` commands are only supported within the code of a template; using them elsewhere has unpredictable results. If they are used together with `\AssignTemplateKeys` then the latter command should come first in the template code.

The main use case for these commands is the situation where there is an argument (normally #1) to the template in which a key/value list can be specified that overwrites the normal settings. In that case one could use

`\SetKnownTemplateKeys{<type>}{<template>}{#1}`

to process this key/value list inside the template.

If `\SetKnownTemplateKeys` is executed and the `<keyvals>` argument contains keys not known to the `<template>` they are simply ignored and stored in the tokenlist `\UnusedTemplateKeys` without generating an error. This way it is possible to apply the same key/val list specified by the user on a document-level command or environment to several templates, which is useful, if the command or environment is implemented by calling several different template instances.

As a variation of that, you can use this key/val list the first time, and for the next template instance use what remains in `\UnusedTemplateKeys` (i.e., the key/val list with only the keys that have not been processed previously). The final processing step could then be `\SetTemplateKeys`, which unconditionally attempts to set the `<keyvals>` received in its third argument. This command complains if any of them are unknown keys. Alternatively, you could use `\SetKnownTemplateKeys` and afterwards

check whether `\UnusedTemplateKeys` is empty.<sup>23</sup>

For example, a list, such as `enumerate`, is made up from a `blockenv`, `block`, `list`, and a `para` template and in the single user-supplied optional argument of `enumerate` key/values for any of these templates might be specified.

In fact, in the particular example of list environments, the supplied key/value list is also saved and then applied to each `\item` which is implemented through an `item` template. This way, one can specify one-off settings for all the items of a single list (on the environment level), as well as to individual items within that list (by specifying them in the optional argument of an `\item`). With `\SetKnownTemplateKeys` and `\SetTemplateKeys` working together, it is possible to provide this flexibility and still alert the user when one of their keys is misspelled.

On the other hand you may want to allow for “misspellings” without generating an error or a warning. For example, if you define a template that accepts only a few keys, you might just want to ignore anything specified in the source when you use this template in place of a different one, without the need to alter the document source. Or you might just generate a warning message, which is easy, given that the unused key/values are available in the `\UnusedTemplateKeys` variable.

---

<code>\DeclareTemplateCopy</code>	<code>\DeclareTemplateCopy</code> <code>{\type}} {\template2}} {\template1}}</code>
-----------------------------------	--

Copies `\template1` of `\type` to a new name `\template2`: the copy can then be edited independent of the original.

## 6 Multiple choices

The `choice` key type implements multiple choice input. At the interface level, only the list of valid choices is needed:

```
\DeclareTemplateInterface { foo } { bar } { 0 }  
  { key-name : choice { A, B, C } }
```

where the choices are given as a comma-list (which must therefore be wrapped in braces). A default value can also be given:

```
\DeclareTemplateInterface { foo } { bar } { 0 }  
  { key-name : choice { A, B, C } = A }
```

At the implementation level, each choice is associated with code, using a nested key-value list.

```
\DeclareTemplateCode { foo } { bar } { 0 }  
{  
  key-name =  
  {  
    A = Code-A ,  
    B = Code-B ,  
    C = Code-C
```

---

<sup>23</sup>Using `\SetTemplateKeys` exposes the inner structure of the template keys when generating an error. This is something one may want to avoid as it can be confusing to the user, especially if several templates are involved. In that case use `\SetKnownTemplateKeys` and afterwards check whether `\UnusedTemplateKeys` is empty; if it is not empty then generate your own error message.

```

    }
  }
  { ... }

```

The two choice lists should match, but in the implementation a special **unknown** choice is also available. This can be used to ignore values and implement an “else” branch:

```

\DeclareTemplateCode { foo } { bar } { 0 }
{
  key-name =
  {
    A      = Code-A ,
    B      = Code-B ,
    C      = Code-C ,
    unknown = Else-code
  }
}
{ ... }

```

The **unknown** entry must be the last one given, and should *not* be listed in the interface part of the template.

For keys which accept the values **true** and **false** both the boolean and choice key types can be used. As template interfaces are intended to prompt clarity at the design level, the boolean key type should be favored, with the choice type reserved for keys which take arbitrary values.

## 7 Instances

After a template is defined it still needs to be put to use. The parameters that it expects need to be defined before it can be used in a document. Every time a template has parameters given to it, an *instance* is created, and this is the code that ends up in the document to perform the typesetting of whatever pieces of information are input into it.

For example, a template might say “here is a section with or without a number that might be centered or left aligned and print its contents in a certain font of a certain size, with a bit of a gap before and after it” whereas an instance declares “this is a section with a number, which is centered and set in 12pt italic with a 10pt skip before and a 12pt skip after it”. Therefore, an instance is just a frozen version of a template with specific settings as chosen by the designer.

---

---

<code>\DeclareInstance</code>	<code>\DeclareInstance</code>
-------------------------------	-------------------------------

<code>{\type}</code>	<code>{\instance}</code>	<code>{\template}</code>	<code>{\parameters}</code>
----------------------	--------------------------	--------------------------	----------------------------

This function uses a `\template` for an `\type` to create an `\instance`. The `\instance` will be set up using the `\parameters`, which will set some of the `\keys` in the `\template`.

As a practical example, consider a type for document sections (which might include chapters, parts, sections, *etc.*), which is called `\sectioning`. One possible template for this type might be called `\basic`, and one instance of this template would be a numbered section. The instance declaration might read:

```
\DeclareInstance { sectioning } { section-num } { basic }
{
  numbered      = true ,
  justification = center ,
  font          =\normalsize\itshape ,
  before-skip   = 10pt ,
  after-skip    = 12pt ,
}
```

Of course, the key names here are entirely imaginary, but illustrate the general idea of fixing some settings.

---

<code>\IfInstanceExistsT</code>	<code>\IfInstanceExistsTF</code>	<code>{\type}</code>	<code>{\instance}</code>	<code>{\true code}</code>	<code>{\false code}</code>
---------------------------------	----------------------------------	----------------------	--------------------------	---------------------------	----------------------------

---

<code>\IfInstanceExistsF</code>
---------------------------------

---

<code>\IfInstanceExistsTF</code>
----------------------------------

Tests if the named `\instance` of a `\type` exists, and then inserts the appropriate code into the input stream.

---

<code>\DeclareInstanceCopy</code>	<code>\DeclareInstanceCopy</code>
-----------------------------------	-----------------------------------

<code>{\type}</code>	<code>{\instance2}</code>	<code>{\instance1}</code>
----------------------	---------------------------	---------------------------

Copies the `\values` for `\instance1` for an `\type` to `\instance2`.

## 8 Document interface

After the instances have been chosen, document commands must be declared to use those instances in the document. `\UseInstance` calls instances directly, and this command should be used internally in document-level mark-up.

---

<code>\UseInstance</code>	<code>\UseInstance</code>
---------------------------	---------------------------

<code>{\type}</code>	<code>{\instance}</code>	<code>\arguments</code>
----------------------	--------------------------	-------------------------

Uses an `\instance` of the `\type`, which will require `\arguments` as determined by the number specified for the `\type`. The `\instance` must have been declared before it can be used, otherwise an error is raised.

---

<code>\UseTemplate</code>	<code>\UseTemplate {&lt;type&gt;} {&lt;template&gt;}</code> <code>{&lt;settings&gt;} &lt;arguments&gt;</code>
---------------------------	--

---

Uses the `<template>` of the specified `<type>`, applying the `<settings>` and absorbing `<arguments>` as detailed by the `<type>` declaration. This in effect is the same as creating an instance using `\DeclareInstance` and immediately using it with `\UseInstance`, but without the instance having any further existence. This command is therefore useful when a template needs to be used only once.

This function can also be used as the argument to `instance` key types:

```
\DeclareInstance { type } { template } { instance }
{
  instance-key =
    \UseTemplate { type2 } { template2 } { <settings> }
}
```

## 9 Changing existing definitions

Template parameters may be assigned specific defaults for instances to use if the instance declaration doesn't explicit set those parameters. In some cases, the document designer will wish to edit these defaults to allow them to “cascade” to the instances. The alternative would be to set each parameter identically for each instance declaration, a tedious and error-prone process.

---

<code>\EditTemplateDefaults</code>	<code>\EditTemplateDefaults</code> <code>{&lt;type&gt;} {&lt;template&gt;} {&lt;new defaults&gt;}</code>
------------------------------------	---

---

Edits the `<defaults>` for a `<template>` for an `<type>`. The `<new defaults>`, given as a key–value list, replace the existing defaults for the `<template>`. This means that the change will apply to instances declared after the editing, but that instances which have already been created are unaffected.

---

<code>\EditInstance</code>	<code>\EditInstance</code> <code>{&lt;type&gt;} {&lt;instance&gt;} {&lt;new values&gt;}</code>
----------------------------	---

---

Edits the `<values>` for an `<instance>` for an `<type>`. The `<new values>`, given as a key–value list, replace the existing values for the `<instance>`. This function is complementary to `\EditTemplateDefaults`: `\EditInstance` changes a single instance while leaving the template untouched.

### 9.1 Expanding the values of keys

To allow the user to apply expansion of values when the key is set, key names can be followed by an expansion specifier. This is given by appending `:` and a single letter specifier to the key name. These letters are the normal argument specifiers for `expl3`, thus they may be one of `n` (redundant but supported), `o`, `V`, `v`, `e`, `N` (again redundant) or `c`. Expansion of a control sequence name is particularly useful when you need to refer to an internal  $\text{\LaTeX} 2_{\epsilon}$  or an L3 programming layer variable, e.g.,

```
key-a:c = @itemdepth , % use \@itemdepth as the value
key-b:v = @itemdepth   % use the current value of \@itemdepth as the value
```

## 10 Getting information about templates and instances

<hr/> <hr/>	<code>\ShowInstanceValues {&lt;type&gt;} {&lt;instance&gt;}</code>
	Shows the <i>&lt;values&gt;</i> for an <i>&lt;instance&gt;</i> of the given <i>&lt;type&gt;</i> at the terminal.
<hr/> <hr/>	<code>\ShowTemplateCode {&lt;type&gt;} {&lt;template&gt;}</code>
	Shows the <i>&lt;code&gt;</i> of a <i>&lt;template&gt;</i> for an <i>&lt;type&gt;</i> in the terminal.
<hr/> <hr/>	<code>\ShowTemplateDefaults {&lt;type&gt;} {&lt;template&gt;}</code>
	Shows the <i>&lt;default&gt;</i> values of a <i>&lt;template&gt;</i> for an <i>&lt;type&gt;</i> in the terminal.
<hr/> <hr/>	<code>\ShowTemplateInterface {&lt;type&gt;} {&lt;template&gt;}</code>
	Shows the <i>&lt;keys&gt;</i> and associated <i>&lt;key types&gt;</i> of a <i>&lt;template&gt;</i> for an <i>&lt;type&gt;</i> in the terminal.
<hr/> <hr/>	<code>\ShowTemplateVariables {&lt;type&gt;} {&lt;template&gt;}</code>
	Shows the <i>&lt;variables&gt;</i> and associated <i>&lt;keys&gt;</i> of a <i>&lt;template&gt;</i> for an <i>&lt;type&gt;</i> in the terminal. Note that <i>code</i> and <i>choice</i> keys do not map directly to variables but to arbitrary code. For <i>choice</i> keys, each valid choice is shown as a separate entry in the list, with the key name and choice separated by a space, for example
	<p>Template 'example' of type 'example' has variable mapping:</p> <pre> &gt; demo unknown =&gt; \def \demo {?} &gt; demo c      =&gt; \def \demo {c} &gt; demo b      =&gt; \def \demo {b} &gt; demo a      =&gt; \def \demo {a}.</pre>

would be shown for a choice key *demo* with valid choices *a*, *b* and *c*, plus code for an *unknown* branch.

## 11 The implementation

```

(End of definition for \\_\_template\_quark\_if\_nil:nTF.)

## 11.2 Testing existence and validity

There are a number of checks needed for either the existence of a type, template or instance. There are also some for the validity of a particular call. All of these are collected up here.

`\_template\_execute\_if\_arg\_agree:nnT`

A test agreement between the number of arguments for the template type and that specified when creating a template. This is not done as a separate conditional for efficiency and better error message

```
43 \cs_new_protected:Npn \_template_execute_if_arg_agree:nnT #1#2#3
44 {
45   \prop_get:NnN \g__template_type_prop {#1} \l__template_tmp_tl
46   \int_compare:nNnTF {#2} = \l__template_tmp_tl
47     {#3}
48   {
49     \msg_error:nneee { template } { argument-number-mismatch }
50     {#1} { \l__template_tmp_tl } {#2}
51   }
52 }
```

*(End of definition for \\_template\_execute\_if\_arg\_agree:nnT.)*

`\_template\_execute\_if\_code\_exist:nnT`

A template is only fully declared if the code has been set up, which can be checked by looking for the template function itself.

```
53 \cs_new_protected:Npn \_template_execute_if_code_exist:nnT #1#2#3
54 {
55   \cs_if_exist:ctF { \c__template_code_root_tl #1 / #2 }
56     {#3}
57   { \msg_error:nnnn { template } { no-template-code } {#1} {#2} }
58 }
```

*(End of definition for \\_template\_execute\_if\_code\_exist:nnT.)*

`\_template\_execute\_if\_keytype\_exist:nT`

`\_template\_execute\_if\_keytype\_exist:VT`

The test for valid keytypes looks for a function to set up the key, which is part of the “code” side of the template definition. This avoids having different lists for the two parts of the process.

```
59 \cs_new_protected:Npn \_template_execute_if_keytype_exist:nT #1#2
60 {
61   \cs_if_exist:ctF { __template_store_value_ #1 :n }
62     {#2}
63   { \msg_error:nnn { template } { unknown-keytype } {#1} }
64 }
65 \cs_generate_variant:Nn \_template_execute_if_keytype_exist:nT { V }
```

*(End of definition for \\_template\_execute\_if\_keytype\_exist:nT.)*

`\_template\_execute\_if\_type\_exist:nT`

To check that a particular type is valid.

```
66 \cs_new_protected:Npn \_template_execute_if_type_exist:nT #1#2
67 {
68   \prop_if_in:NnTF \g__template_type_prop {#1}
69     {#2}
70   { \msg_error:nnn { template } { unknown-type } {#1} }
71 }
```

*(End of definition for \\_template\_execute\_if\_type\_exist:nT.)*

`\_template\_execute\_if\_keys\_exist:nnT` To check that the keys for a template have been set up before trying to create any code, a simple check for the correctly-named keytype property list.

```

72 \cs_new_protected:Npn \_template\_if\_keys\_exist:nnT #1#2#3
73 {
74   \cs_if_exist:cTF { \c__template_keytypes_root_tl #1 / #2 }
75   {#3}
76   { \msg_error:nnnn { template } { unknown-template } {#1} {#2} }
77 }

```

(End of definition for `\_template\_execute\_if\_keys\_exist:nnT`.)

`\_template\_if\_key\_value:nTF` Tests for the first token in a string being `\KeyValue`.

`\_template\_if\_key\_value:VTF`

```

78 \prg_new_conditional:Npnn \_template\_if\_key\_value:n #1 { T , F , TF }
79 {
80   \str_if_eq:noTF { \KeyValue } { \tl_head:w #1 \q_nil \q_stop }
81   \prg_return_true:
82   \prg_return_false:
83 }
84 \prg_generate_conditional_variant:Nnn \_template\_if\_key\_value:n { V } { T , F , TF }

```

(End of definition for `\_template\_if\_key\_value:nTF`.)

`\_template\_if\_instance\_exist:nnTF` Testing for an instance

```

85 \prg_new_conditional:Npnn \_template\_if\_instance\_exist:nn #1#2 { T, F, TF }
86 {
87   \cs_if_exist:cTF { \c__template_instances_root_tl #1 / #2 }
88   \prg_return_true:
89   \prg_return_false:
90 }

```

(End of definition for `\_template\_if\_instance\_exist:nnTF`.)

`\_template\_if\_use\_template:nTF` Tests for the first token in a string being `\UseTemplate`.

```

91 \prg_new_conditional:Npnn \_template\_if\_use\_template:n #1 { TF }
92 {
93   \str_if_eq:noTF { \UseTemplate } { \tl_head:w #1 \q_nil \q_stop }
94   \prg_return_true:
95   \prg_return_false:
96 }

```

(End of definition for `\_template\_if\_use\_template:nTF`.)

## 11.3 Saving and recovering property lists

The various property lists for templates have to be shuffled in and out of storage.

`\_template\_store\_defaults:nn`

`\_template\_store\_keytypes:nn`

The defaults and keytypes are transferred from the scratch property lists to the “proper” lists for the template being created.

`\_template\_store\_values:nn`

`\_template\_store\_vars:nn`

```

97 \cs_new_protected:Npn \_template\_store\_defaults:nn #1#2
98 {
99   \debug_suspend:
100   \prop_gc_clear_new:c { \c__template_defaults_root_tl #1 / #2 }
101   \prop_gset_eq:cN { \c__template_defaults_root_tl #1 / #2 }
102   \l__template_values_prop

```

```

103     \debug_resume:
104 }
105 \cs_new_protected:Npn \__template_store_keytypes:nn #1#2
106 {
107     \debug_suspend:
108     \prop_if_exist:cTF { \c__template_keytypes_root_tl #1 / #2 }
109     {
110         \msg_info:nnnn { template } { declare-template-interface } {#1} {#2}
111         \prop_gclear:c { \c__template_keytypes_root_tl #1 / #2 }
112     }
113     { \prop_new:c { \c__template_keytypes_root_tl #1 / #2 } }
114     \prop_gset_eq:cN { \c__template_keytypes_root_tl #1 / #2 }
115     \l__template_keytypes_prop
116     \seq_gclear_new:c { \c__template_key_order_root_tl #1 / #2 }
117     \seq_gset_eq:cN { \c__template_key_order_root_tl #1 / #2 }
118     \l__template_key_order_seq
119     \debug_resume:
120 }
121 \cs_new_protected:Npn \__template_store_values:nn #1#2
122 {
123     \debug_suspend:
124     \prop_clear_new:c { \c__template_values_root_tl #1 / #2 }
125     \prop_set_eq:cN { \c__template_values_root_tl #1 / #2 }
126     \l__template_values_prop
127     \debug_resume:
128 }
129 \cs_new_protected:Npn \__template_store_vars:nn #1#2
130 {
131     \debug_suspend:
132     \prop_gclear_new:c { \c__template_vars_root_tl #1 / #2 }
133     \prop_gset_eq:cN { \c__template_vars_root_tl #1 / #2 }
134     \l__template_vars_prop
135     \debug_resume:
136 }

```

(End of definition for \\_\_template\_store\_defaults:nn and others.)

```

\__template_recover_defaults:nn
\__template_recover_keytypes:nn
\__template_recover_values:nn
\__template_recover_vars:nn

```

Recovering the stored data for a template is rather less complex than storing it. All that happens is the data is transferred from the permanent to the scratch storage. However, we need to check the scratch storage does exist.

```

137 \cs_new_protected:Npn \__template_recover_defaults:nn #1#2
138 {
139     \prop_if_exist:cTF
140     { \c__template_defaults_root_tl #1 / #2 }
141     {
142         \prop_set_eq:Nc \l__template_values_prop
143         { \c__template_defaults_root_tl #1 / #2 }
144     }
145     { \prop_clear:N \l__template_values_prop }
146 }
147 \cs_new_protected:Npn \__template_recover_keytypes:nn #1#2
148 {
149     \prop_if_exist:cTF
150     { \c__template_keytypes_root_tl #1 / #2 }

```

```

151     {
152         \prop_set_eq:Nc \l__template_keytypes_prop
153         { \c__template_keytypes_root_tl #1 / #2 }
154     }
155     { \prop_clear:N \l__template_keytypes_prop }
156 \seq_if_exist:cTF { \c__template_key_order_root_tl #1 / #2 }
157     {
158         \seq_set_eq:Nc \l__template_key_order_seq
159         { \c__template_key_order_root_tl #1 / #2 }
160     }
161     { \seq_clear:N \l__template_key_order_seq }
162 }
163 \cs_new_protected:Npn \__template_recover_values:nn #1#2
164 {
165     \prop_if_exist:cTF
166     { \c__template_values_root_tl #1 / #2 }
167     {
168         \prop_set_eq:Nc \l__template_values_prop
169         { \c__template_values_root_tl #1 / #2 }
170     }
171     { \prop_clear:N \l__template_values_prop }
172 }
173 \cs_new_protected:Npn \__template_recover_vars:nn #1#2
174 {
175     \prop_if_exist:cTF
176     { \c__template_vars_root_tl #1 / #2 }
177     {
178         \prop_set_eq:Nc \l__template_vars_prop
179         { \c__template_vars_root_tl #1 / #2 }
180     }
181     { \prop_clear:N \l__template_vars_prop }
182 }

```

(End of definition for `\__template_recover_defaults:nn` and others.)

## 11.4 Creating new template types

`\__template_define_type:nn`  
`\__template_declare_type:nn`

Although the type is the “top level” of the template system, it is actually very easy to implement. All that happens is that the number of arguments required is recorded, indexed by the name of the type.

```

183 \cs_new_protected:Npn \__template_define_type:nn #1#2
184 {
185     \prop_if_in:NnTF \g__template_type_prop {#1}
186     { \msg_error:nnn { template } { type-already-defined } {#1} }
187     { \__template_declare_type:nn {#1} {#2} }
188 }
189 \cs_new_protected:Npn \__template_declare_type:nn #1#2
190 {
191     \int_set:Nn \l__template_tmp_int {#2}
192     \int_compare:nTF { 0 <= \l__template_tmp_int <= 9 }
193     {
194         \msg_info:nnnV { template } { declare-type }
195         {#1} \l__template_tmp_int
196         \prop_gput:NnV \g__template_type_prop {#1}

```

```

197         \l__template_tmp_int
198     }
199     {
200         \msg_error:nnnV { template } { bad-number-of-arguments }
201         {#1} \l__template_tmp_int
202     }
203 }

```

(End of definition for `\__template_define_type:nn` and `\__template_declare_type:nn`.)

## 11.5 Design part of template declaration

The “design” part of a template declaration defines the general behaviour of each key, and possibly a default value. However, it does not include the implementation. This means that what happens here is the two properties are saved to appropriate lists, which can then be used later to recover the information when implementing the keys.

`\__template_declare_template_keys:nnnn`

The main function for the “design” part of creating a template starts by checking that the type exists and that the number of arguments required agree. If that is all fine, then the two storage areas for defaults and keytypes are initialised. The mechanism is then set up for the `l3keys` module to actually parse the keys. Finally, the code hands of to the storage routine to save the parsed information properly.

```

204 \cs_new_protected:Npn \__template_declare_template_keys:nnnn #1#2#3#4
205 {
206     \__template_execute_if_type_exist:nT {#1}
207     {
208         \__template_execute_if_arg_agree:nnT {#1} {#3}
209         {
210             \prop_clear:N \l__template_values_prop
211             \prop_clear:N \l__template_keytypes_prop
212             \seq_clear:N \l__template_key_order_seq
213             \keyval_parse:NNn
214             \__template_parse_keys_elt:n \__template_parse_keys_elt:nn {#4}
215             \__template_store_defaults:nn {#1} {#2}
216             \__template_store_keytypes:nn {#1} {#2}
217         }
218     }
219 }

```

(End of definition for `\__template_declare_template_keys:nnnn`.)

`\__template_parse_keys_elt:n`

`\__template_parse_keys_elt_aux:n`

`\__template_parse_keys_elt_aux:`

Processing the key part of the key–value pair is always carried out using this function, even if a value was found. First, the key name is separated from the keytype, and if necessary the keytype is separated into two parts. This information is then used to check that the keytype is valid, before storing the keytype (plus argument if necessary) as a property of the key name. The key name is also stored (in braces) in the token list to record the order the keys are defined in.

```

220 \cs_new_protected:Npn \__template_parse_keys_elt:n #1
221 {
222     \__template_split_keytype:n {#1}
223     \bool_if:NF \l__template_error_bool
224     {
225         \__template_execute_if_keytype_exist:VT \l__template_keytype_tl

```

```

226     {
227         \seq_map_function:NN \c__template_keytypes_arg_seq
228         \__template_parse_keys_elt_aux:n
229         \bool_if:NF \l__template_error_bool
230         {

319   }
320 }

```

(End of definition for `\__template_split_keytype:n` and `\__template_split_keytype_aux:w`.)

`\__template_split_keytype_arg:n`  
`\__template_split_keytype_arg:V`  
`\__template_split_keytype_arg_aux:n`  
`\__template_split_keytype_arg_aux:w`

The second stage of sorting out the keytype is to check for an argument. As there is no convenient delimiting token to look for, a check is made instead for each possible text value for the keytype. To keep things faster, this only involves the keytypes that need an argument. If a match is made, then a check is also needed to see that it is at the start of the keytype information. All being well, the split can then be applied. Any non-matching keytypes are assumed to be “correct” as given, and are left alone (this is checked by other code).

```

(End of definition for `\__template_split_keytype_arg:n`, `\__template_split_keytype_arg_aux:n`,  
and `\__template_split_keytype_arg_aux:w`.)

### 11.5.1 Storing values

As `ltxtemplates` pre-processes key values for efficiency reasons, there is a need to convert the values given as defaults into “ready to use” data. The same general idea is true when an instance is declared. However, assignments are not made until an instance is used, and so there has to be some intermediate storage. Furthermore, the ability to delay evaluation of results is needed. To achieve these aims, a series of “process and store” functions are defined here.

All of the information about the key (the key name and the keytype) is already stored as variables. The same property list is always used to store the data, meaning that the only argument required is the value to be processed and potentially stored.

```

\__template_store_value_boolean:n
353 \cs_new_protected:Npn \__template_store_value_boolean:n #1
354   { \prop_put:Non \l__template_values_prop \l__template_key_name_tl {#1} }

(End of definition for \__template_store_value_boolean:n.)

(End of definition for \__template_store_value_aux:Nn and others.)

```

## 11.6 Implementation part of template declaration

The main function for implementing a template starts with a couple of simple checks to make sure that there are no obvious mistakes: the number of arguments must agree and the template keys must have been declared.

```

\__template_declare_template_code:nnnnn
\__template_declare_template_code:nnnn
375 \cs_new_protected:Npn \__template_declare_template_code:nnnnn #1#2#3#4#5
376   {
377     \__template_execute_if_type_exist:nT {#1}
378     {
379       \__template_execute_if_arg_agree:nnT {#1} {#3}
380       {
381         \__template_if_keys_exist:nnT {#1} {#2}
382         {
383           \__template_store_key_implementation:nnn {#1} {#2} {#4}
384           \str_if_in:nnTF {#5} { AssignTemplateKeys }

```

```

385         {
386             \regex_match:nnTF { \c { AssignTemplateKeys } } {#5}
387             { \__template_declare_template_code:nnnn {#1} {#2} {#3} {#5} }
388             {
389                 \__template_declare_template_code:nnnn
390                 {#1} {#2} {#3} { \AssignTemplateKeys #5 }
391             }
392         }
393     {
394         \__template_declare_template_code:nnnn
395         {#1} {#2} {#3} { \AssignTemplateKeys #5 }
396     }
397 }
398 }
399 }
400 }
401 \cs_new_protected:Npn \__template_declare_template_code:nnnn #1#2#3#4
402 {
403     \cs_if_exist:cT { \c__template_code_root_tl #1 / #2 }
404     { \msg_info:nnnn { template } { declare-template-code } {#1} {#2} }
405     \cs_generate_from_arg_count:cNnn
406     { \c__template_code_root_tl #1 / #2 }
407     \cs_gset_protected:Npn {#3} {#4}
408 }

```

(End of definition for \\_\_template\_declare\_template\_code:nnnn and  
\\_\_template\_declare\_template\_code:nnnn.)

\\_\_template\_store\_key\_implementation:nnn

Actually storing the implementation part of a template is quite easy as it only requires the list of keys given to be turned into a property list. There is also some error-checking to do, hence the need to have the list of defined keytypes available. In certain cases (when choices are involved) parsing the key results in changes to the default values. That is why they are loaded and then saved again.

```

409 \cs_new_protected:Npn \__template_store_key_implementation:nnn #1#2#3
410 {
411     \__template_recover_defaults:nn {#1} {#2}
412     \__template_recover_keytypes:nn {#1} {#2}
413     \prop_clear:N \l__template_vars_prop
414     \keyval_parse:nnn
415     { \__template_parse_vars_elt:n } { \__template_parse_vars_elt:nnn { #1 / #2 } } {#3}
416     \__template_store_vars:nn {#1} {#2}
417     \prop_map_inline:Nn \l__template_keytypes_prop
418     { \msg_error:nnnnn { template } { key-not-implemented } {##1} {#2} {#1} }
419 }

```

(End of definition for \\_\_template\_store\_key\_implementation:nnn.)

\\_\_template\_parse\_vars\_elt:n

At the implementation stage, every key must have a value given. So this is an error function.

```

420 \cs_new_protected:Npn \__template_parse_vars_elt:n #1
421 { \msg_error:nnn { template } { key-no-variable } {#1} }

```

(End of definition for \\_\_template\_parse\_vars\_elt:n.)

```

\__template_parse_vars_elt:nnn
\__template_parse_vars_elt_aux:nn
\__template_parse_vars_elt_aux:nw
\__template_parse_vars_elt_aux:nnn
\__template_parse_vars_elt_aux:nne
\__template_parse_vars_elt_key:nn

```

The actual storage part here is very simple: the storage bin name is placed into the property list. At the same time, a comparison is made with the keytypes defined earlier: if there is a mismatch then an error is raised.

```

422 \cs_new_protected:Npn \__template_parse_vars_elt:nnn #1#2#3
423 {
424   \tl_set:Nx \l__template_key_name_tl

```

(End of definition for `\__template_implement_choice_elt:nnn` and others.)

## 11.7 Editing template defaults

```
\__template_edit_defaults:nnn
```

Editing the template defaults means getting the values back out of the store, then parsing the list of new values before putting the updated list back into storage.

```
606 \cs_new_protected:Npn \__template_edit_defaults:nnn #1#2#3
```

```

607 {
608   \__template_if_keys_exist:nnT {#1} {#2}
609   {
610     \__template_recover_defaults:nn {#1} {#2}
611     \__template_parse_values:nnn {#1} {#2} {#3}
612     \__template_store_defaults:nn {#1} {#2}
613   }
614 }

```

(End of definition for \\_\_template\_edit\_defaults:nnn.)

\\_\_template\_parse\_values:nnn The routine to parse values is the same for both editing a template and setting up an instance. So the code here does only the minimum necessary for reading the values.

```

615 \cs_new_protected:Npn \__template_parse_values:nnn #1#2#3
616 {
617   \__template_recover_keytypes:nn {#1} {#2}
618   \keyval_parse:NNn
619   \__template_parse_values_elt:n \__template_parse_values_elt:nn {#3}
620 }

```

(End of definition for \\_\_template\_parse\_values:nnn.)

\\_\_template\_parse\_values\_elt:n Every key needs a value, so this is just an error routine.

```

621 \cs_new_protected:Npn \__template_parse_values_elt:n #1
622 {
623   \bool_set_true:N \l__template_error_bool
624   \msg_error:nnn { template } { key-no-value } {#1}
625 }

```

(End of definition for \\_\_template\_parse\_values\_elt:n.)

\\_\_template\_parse\_values\_elt:nn To store the value, find the keytype then call the saving function. These need the current key name, stored in \l\_\_template\_key\_name\_tl.

```

674   { \c__template_code_root_tl #1 / #3 }
675 }

```

(End of definition for \\_\_template\_template\_set\_eq:nnn.)

## 11.8 Creating instances of templates

\\_\_template\_declare\_instance:nnnn  
\\_\_template\_declare\_instance\_aux:nnnn

Making an instance has two distinct parts. First, the keys given are parsed to transfer the values into the structured data format used internally. This allows the default and given values to be combined with no repetition. In the second step, the structured data is converted to pre-defined variable assignments, and these are stored in the function for the instance.

```

676 \cs_new_protected:Npn \__template_declare_instance:nnnn #1#2#3#4
677 {
678   \__template_execute_if_code_exist:nnT {#1} {#2}
679   {
680     \__template_recover_defaults:nn {#1} {#2}
681     \__template_recover_vars:nn {#1} {#2}
682     \__template_declare_instance_aux:nnnn {#1} {#2} {#3} {#4}
683   }
684 }
685 \cs_new_protected:Npn \__template_declare_instance_aux:nnnn #1#2#3#4
686 {

```

```

687 \bool_set_false:N \l__template_error_bool
688 \__template_parse_values:nnn {#1} {#2} {#4}
689 \bool_if:NF \l__template_error_bool
690 {
691   \prop_put:Nnn \l__template_values_prop { from-template } {#2}
692   \__template_store_values:nn {#1} {#3}
693   \__template_convert_to_assignments:
694   \cs_if_exist:cT { \c__template_instances_root_tl #1 / #3 }
695     { \msg_info:nnnn { template } { declare-instance } {#3} {#1} }
696   \cs_set_protected:cpe { \c__template_instances_root_tl #1 / #3 }
697     {
698       \exp_not:N \__template_assignments_push:n
699       { \exp_not:V \l__template_assignments_tl }
700       \exp_not:c { \c__template_code_root_tl #1 / #2 }
701     }
702 }
703 }

```

(End of definition for \\_\_template\_declare\_instance:nnnn and  
\\_\_template\_declare\_instance\_aux:nnnn.)

\\_\_template\_instance\_set\_eq:nnn Copy-paste an instance.

```

704 \cs_new_protected:Npn \__template_instance_set_eq:nnn #1#2#3
705 {
706   \__template_if_instance_exist:nnTF {#1} {#3}

725     {#1} \l__template_tmp_tl {#2} {#3}
726   }
727   { \msg_error:nnnn { template } { unknown-instance } {#1} {#2} }
728 }
729 \cs_new_protected:Npn \__template_edit_instance_aux:nnnn #1#2#3#4
730 {
731   \__template_recover_vars:nn {#1} {#2}

```

```

732   \__template_declare_instance_aux:nnnn {#1} {#2} {#3} {#4}
733   }
734   \cs_generate_variant:Nn \__template_edit_instance_aux:nnnn { nV }

```

(End of definition for \\_\_template\_edit\_instance:nnn and \\_\_template\_edit\_instance\_aux:nnnn.)

```

\__template_convert_to_assignments:
\__template_convert_to_assignments_aux:n
\__template_convert_to_assignments_aux:nn
\__template_convert_to_assignments_aux:nV

```

The idea on converting to a set of assignments is to loop over each key, so that the loop order follows the declaration order of the keys. This is done using a sequence as property lists are not “ordered”.

```

735   \cs_new_protected:Npn \__template_convert_to_assignments:
736   {
737     \tl_clear:N \l__template_assignments_tl
738     \seq_map_function:NN \l__template_key_order_seq
739     \__template_convert_to_assignments_aux:n
740   }
741   \cs_new_protected:Npn \__template_convert_to_assignments_aux:n #1
742   {
743     \prop_get:NnN \l__template_keytypes_prop {#1} \l__template_tmp_tl
744     \__template_convert_to_assignments_aux:nV {#1} \l__template_tmp_tl
745   }

```

The second auxiliary function actually does the work. The arguments here are the key name (#1) and the keytype (#2). From those, the value to assign and the name of the appropriate variable are recovered. A bit of work is then needed to sort out keytypes with arguments (for example instances), and to look for global assignments. Once that is done, a hand-off can be made to the handler for the relevant keytype.

```

746   \cs_new_protected:Npn \__template_convert_to_assignments_aux:nn #1#2
747   {
748     \prop_get:NnNT \l__template_values_prop {#1} \l__template_value_tl
749     {
750       \prop_get:NnNTF \l__template_vars_prop {#1} \l__template_var_tl
751       {
752         \__template_split_keytype_arg:n {#2}
753         \str_if_eq:VnF \l__template_keytype_tl { choice }
754         {
755           \str_if_eq:VnF \l__template_keytype_tl { code }
756           { \__template_find_global: }
757         }
758         \tl_set:Nn \l__template_key_name_tl {#1}
759         \cs_if_exist_use:cF { __template_assign_ \l__template_keytype_tl : }
760         { \__template_assign_variable: }
761       }
762       { \msg_error:nnn { template } { unknown-attribute } {#1} }
763     }
764   }
765   \cs_generate_variant:Nn \__template_convert_to_assignments_aux:nn { nV }

```

(End of definition for \\_\_template\_convert\_to\_assignments:,  
\\_\_template\_convert\_to\_assignments\_aux:n, and \\_\_template\_convert\_to\_assignments\_aux:nn.)

```

\__template_find_global:
\__template_find_global_aux:w

```

Global assignments should have the phrase global at the front. This is pretty easy to find: no other error checking, though.

```

766   \cs_new_protected:Npn \__template_find_global:
767   {

```

```

768 \bool_set_false:N \l__template_global_bool
769 \tl_if_in:onT \l__template_var_tl { global }
770 {
771   \exp_after:wN \__template_find_global_aux:w \l__template_var_tl \s__template_stop
772 }
773 }
774 \cs_new_protected:Npn \__template_find_global_aux:w #1 global #2 \s__template_stop
775 {
776   \tl_set:Nn \l__template_var_tl {#2}
777   \bool_set_true:N \l__template_global_bool
778 }

```

(End of definition for \\_\_template\_find\_global: and \\_\_template\_find\_global\_aux:w.)

## 11.9 Using templates directly

\\_\_template\_use\_template:nnn Directly use a template with a particular parameter setting. This is also picked up if used in a nested fashion inside a parameter list. The idea is essentially the same as creating an instance, just with no saving of the result.

```

779 \cs_new_protected:Npn \__template_use_template:nnn #1#2#3
780 {
781   \__template_execute_if_code_exist:nnT {#1} {#2}
782   {
783     \__template_recover_defaults:nn {#1} {#2}
784     \__template_recover_vars:nn {#1} {#2}
785     \__template_parse_values:nnn {#1} {#2} {#3}
786     \__template_convert_to_assignments:
787     \use:c { \c__template_code_root_tl #1 / #2 }
788   }
789 }

```

(End of definition for \\_\_template\_use\_template:nnn.)

## 11.10 Assigning values to variables

\\_\_template\_assign\_boolean: Setting a Boolean value is slightly different to everything else as the value can be used to work out which set function to call. As long as there is no need to recover things from another variable, everything is pretty easy. If there is, then we need to allow for the fact that the recovered value here will *not* be expandable, so needs to be converted to something that is.

```

790 \cs_new_protected:Npn \__template_assign_boolean:
791 {
792   \bool_if:NTF \l__template_global_bool
793   { \__template_assign_boolean_aux:n { bool_gset } }
794   { \__template_assign_boolean_aux:n { bool_set } }
795 }
796 \cs_new_protected:Npn \__template_assign_boolean_aux:n #1
797 {
798   \__template_if_key_value:VTF \l__template_value_tl
799   {
800     \__template_key_to_value:
801     \tl_put_right:Ne \l__template_assignments_tl
802     {

```

```

803         \exp_not:c { #1 _eq:NN }
804         \exp_not:V \l__template_var_tl
805         \exp_not:V \l__template_value_tl
806     }
807 }
808 {
809     \tl_put_right:Ne \l__template_assignments_tl
810     {
811         \exp_not:c { #1 _ \l__template_value_tl :N }
812         \exp_not:V \l__template_var_tl
813     }
814 }
815 }

```

(End of definition for \\_\_template\_assign\_boolean: and \\_\_template\_assign\_boolean\_aux:n.)

\\_\_template\_assign\_choice: The idea here is to find either the choice as-given or else the special `unknown` choice, and to copy the appropriate code across.

```

\__template_assign_choice_aux:nF
\__template_assign_choice_aux:eF
816 \cs_new_protected:Npn \__template_assign_choice:
817 {
818     \__template_assign_choice_aux:eF
819     { \l__template_key_name_tl \c_space_tl \l__template_value_tl }
820     {
821         \__template_assign_choice_aux:eF
822         { \l__template_key_name_tl \c_space_tl unknown }
823         {
824             \prop_get:NVN \l__template_keytypes_prop \l__template_key_name_tl
825             \l__template_tmp_tl
826             \__template_split_keytype_arg:V \l__template_tmp_tl
827             \msg_error:nnVV { template } { unknown-choice }
828             \l__template_key_name_tl
829             \l__template_value_tl
830         }
831     }
832 }
833 \cs_new_protected:Npn \__template_assign_choice_aux:nF #1
834 {
835     \prop_get:NnNTF \l__template_vars_prop {#1} \l__template_tmp_tl
836     { \tl_put_right:NV \l__template_assignments_tl \l__template_tmp_tl }
837 }
838 \cs_generate_variant:Nn \__template_assign_choice_aux:nF { e }

```

(End of definition for \\_\_template\_assign\_choice: and \\_\_template\_assign\_choice\_aux:nF.)

\\_\_template\_assign\_function: This looks a bit messy but is only actually one function.

```

\__template_assign_function_aux:N
839 \cs_new_protected:Npn \__template_assign_function:
840 {
841     \bool_if:NTF \l__template_global_bool
842     { \__template_assign_function_aux:N \cs_gset:Npn }
843     { \__template_assign_function_aux:N \cs_set:Npn }
844 }
845 \cs_new_protected:Npn \__template_assign_function_aux:N #1
846 {
847     \tl_put_right:Ne \l__template_assignments_tl

```

```

848     {
849         \cs_generate_from_arg_count:NNnn
850         \exp_not:V \l__template_var_tl
851         \exp_not:N #1
852         { \exp_not:V \l__template_keytype_arg_tl }
853         { \exp_not:V \l__template_value_tl }
854     }
855 }

```

(End of definition for `\__template_assign_function:` and `\__template_assign_function_aux:N`.)

`\__template_assign_instance:` Using an instance means adding the appropriate function creation to the tl. No checks are made at this stage, so if the instance is not valid then errors will arise later.

```

856 \cs_new_protected:Npn \__template_assign_instance:
857 {
858     \bool_if:NTF \l__template_global_bool
859     { \__template_assign_instance_aux:N \cs_gset_protected:Npn }
860     { \__template_assign_instance_aux:N \cs_set_protected:Npn }
861 }
862 \cs_new_protected:Npn \__template_assign_instance_aux:N #1
863 {
864     \tl_put_right:Ne \l__template_assignments_tl
865     {
866         \exp_not:N #1 \exp_not:V \l__template_var_tl
867         {
868             \__template_use_instance:nn
869             { \exp_not:V \l__template_keytype_arg_tl }
870             { \exp_not:V \l__template_value_tl }
871         }
872     }
873 }

```

(End of definition for `\__template_assign_instance:` and `\__template_assign_instance_aux:N`.)

`\__template_assign_variable:` A general-purpose function for all of the other assignments. As long as the value is not coming from another variable, the stored value is simply transferred for output. We use V-type expansion for the `\KeyValue` case: for token lists this is essential, whilst for register-based variables, it does no harm and avoids needing a low-level test.

```

874 \cs_new_protected:Npn \__template_assign_variable:
875 {
876     \exp_args:Ne \__template_assign_variable:n
877     {
878         \__template_map_var_type:
879         -
880         \bool_if:NT \l__template_global_bool { g }
881         set:N
882     }
883 }

```

Notice we need a V-type variant for each (g)set operation here: these need to be provided by `expl3`.

```

884 \cs_new_protected:Npn \__template_assign_variable:n #1
885 {
886     \__template_if_key_value:VTF \l__template_value_tl

```

```

887 {
888   \__template_key_to_value:
889   \tl_put_right:Ne \l__template_assignments_tl
890   {
891     \exp_not:c { #1 V } \exp_not:V \l__template_var_tl
892     \exp_not:V \l__template_value_tl
893   }
894 }
895 {
896   \tl_put_right:Ne \l__template_assignments_tl
897   {
898     \exp_not:c { #1 n } \exp_not:V \l__template_var_tl
899     { \exp_not:V \l__template_value_tl }
900   }
901 }
902 }

```

(End of definition for \\_\_template\_assign\_variable: and \\_\_template\_assign\_variable:n.)

```

\__template_key_to_value:
  \__template_key_to_value_auxi:w
  \__template_key_to_value_auxii:w

```

The idea here is to recover the attribute value of another key. To do that, the marker is removed and a look up takes place. If this is successful, then the name of the variable of the attribute is returned. This assumes that the value will be used in context where it will be converted to a value, for example when setting a number. There is also a need to check in case the copied value happens to be global.

```

903 \cs_new_protected:Npn \__template_key_to_value:
904 { \exp_after:wN \__template_key_to_value_auxi:w \l__template_value_tl }
905 \cs_new_protected:Npn \__template_key_to_value_auxi:w \KeyValue #1
906 {
907   \tl_set:Ne \l__template_tmp_tl { \tl_trim_spaces:e { \tl_to_str:n {#1} } }
908   \prop_get:NVNTF \l__template_vars_prop \l__template_tmp_tl
909   \l__template_value_tl
910   {
911     \exp_after:wN \__template_key_to_value_auxii:w \l__template_value_tl
912     \s__template_mark global \q__template_nil \s__template_stop
913   }
914   { \msg_error:nnV { template } { unknown-attribute } \l__template_tmp_tl }
915 }
916 \cs_new_protected:Npn \__template_key_to_value_auxii:w #1 global #2#3 \s__template_stop
917 {
918   \__template_quark_if_nil:NF #2
919   { \tl_set:Nn \l__template_value_tl {#2} }
920 }

```

(End of definition for \\_\_template\_key\_to\_value:, \\_\_template\_key\_to\_value\_auxi:w, and \\_\_template\_key\_to\_value\_auxii:w.)

## 11.11 Using instances

```

\__template_use_instance:nn
  \__template_use_instance_aux:nNnnn
  \__template_use_instance_aux:nn

```

Using an instance is just a question of finding the appropriate function. If nothing is found, an error is raised. One complication is that if the first token of argument #2 is \UseTemplate then that is also valid. There is an error-test to make sure that the types agree, and if so the template is used directly.

```

921 \cs_new_protected:Npn \__template_use_instance:nn #1#2
922 {

```

```

923   \__template_if_use_template:nTF {#2}
924   { \__template_use_instance_aux:nNnnn {#1} #2 }
925   { \__template_use_instance_aux:nn {#1} {#2} }
926 }
927 \cs_new_protected:Npn \__template_use_instance_aux:nNnnn #1#2#3#4#5
928 {
929   \str_if_eq:nnTF {#1} {#3}
930   { \__template_use_template:nnn {#3} {#4} {#5} }
931   { \msg_error:nnnn { template } { type-mismatch } {#1} {#3} }
932 }
933 \cs_new_protected:Npn \__template_use_instance_aux:nn #1#2
934 {
935   \__template_if_instance_exist:nnTF {#1} {#2}
936   { \use:c { \c__template_instances_root_tl #1 / #2 } }
937   { \msg_error:nnnn { template } { unknown-instance } {#1} {#2} }
938 }

(End of definition for \__template_use_instance:nn, \__template_use_instance_aux:nNnnn, and
 \__template_use_instance_aux:nn.)

```

## 11.12 Assignment manipulation

A few functions to transfer assignments about, as this is needed by `\AssignTemplateKeys`.

`\__template_assignments_pop:` To actually use the assignments.

```

939 \cs_new:Npn \__template_assignments_pop: { \l__template_assignments_tl }

(End of definition for \__template_assignments_pop:.)

```

`\__template_assignments_push:n` Here, the assignments are stored for later use.

```

940 \cs_new_protected:Npn \__template_assignments_push:n #1
941 { \tl_set:Nn \l__template_assignments_tl {#1} }

(End of definition for \__template_assignments_push:n.)

```

## 11.13 Showing templates and instances

`\__template_show_code:nn` Showing the code for a template is just a translation of `\cs_show:c`.

```

942 \cs_new_protected:Npn \__template_show_code:nn #1#2
943 { \cs_show:c { \c__template_code_root_tl #1 / #2 } }

(End of definition for \__template_show_code:nn.)

```

`\__template_show_defaults:nn` A modified version of the property-list printing code, such that the output refers to templates and instances rather than to the underlying structures.

`\__template_show_keytypes:nn`

`\__template_show_vars:nn`

`\__template_show:Nnnn`

```

944 \cs_new_protected:Npn \__template_show_defaults:nn #1#2
945 {
946   \__template_if_keys_exist:nnT {#1} {#2}
947   {
948     \__template_recover_defaults:nn {#1} {#2}
949     \__template_show:Nnnn \l__template_values_prop
950     {#1} {#2} { default~values }
951   }
952 }

```

```

953 \cs_new_protected:Npn \__template_show_keytypes:nn #1#2
954 {
955   \__template_if_keys_exist:nnT {#1} {#2}
956   {
957     \__template_recover_keytypes:nn {#1} {#2}
958     \__template_show:Nnnn \l__template_keytypes_prop
959     {#1} {#2} { interface }
960   }
961 }
962 \cs_new_protected:Npn \__template_show_vars:nn #1#2
963 {
964   \__template_execute_if_code_exist:nnT {#1} {#2}
965   {
966     \__template_recover_vars:nn {#1} {#2}
967     \__template_show:Nnnn \l__template_vars_prop
968     {#1} {#2} { variable~mapping }
969   }
970 }
971 \cs_new_protected:Npn \__template_show:Nnnn #1#2#3#4
972 {
973   \msg_show:nneeee { template } { show-attribute }
974   { \tl_to_str:n {#2} }
975   { \tl_to_str:n {#3} }
976   { \tl_to_str:n {#4} }
977   { \prop_map_function:NN #1 \msg_show_item_unbraced:nn }
978 }

```

*(End of definition for \\_\_template\_show\_defaults:nn and others.)*

\\_\_template\_show\_values:nn Instance values are a little more complex, as is the template to consider.

```

979 \cs_new_protected:Npn \__template_show_values:nn #1#2
980 {
981   \__template_if_instance_exist:nnT {#1} {#2}
982   {
983     \__template_recover_values:nn {#1} {#2}
984     \msg_show:nneee { template } { show-values }
985     { \tl_to_str:n {#1} }
986     { \tl_to_str:n {#2} }
987     {
988       \prop_map_function:NN \l__template_values_prop
989       \msg_show_item_unbraced:nn
990     }
991   }
992 }

```

*(End of definition for \\_\_template\_show\_values:nn.)*

1221 \cs_new_protected:Npn \ShowInstanceValues #1#2
1222   { \__template_show_values:nn {#1} {#2} }

```

(End of definition for `\ShowTemplateCode` and others. These functions are documented on page 361.)

```

\IfInstanceExistsT    More direct translation.
\IfInstanceExistsF    1223 \cs_new:Npn \IfInstanceExistsTF #1#2
\IfInstanceExistsTF   1224   { \__template_if_instance_exist:nnTF {#1} {#2} }
1225 \cs_new:Npn \IfInstanceExistsT #1#2
1226   { \__template_if_instance_exist:nnT {#1} {#2} }
1227 \cs_new:Npn \IfInstanceExistsF #1#2
1228   { \__template_if_instance_exist:nnF {#1} {#2} }

```

(End of definition for `\IfInstanceExistsT`, `\IfInstanceExistsF`, and `\IfInstanceExistsTF`. These functions are documented on page 359.)

**\KeyValue** Simply dump the argument when executed: this should not happen.

```

1229 \cs_new_protected:Npn \KeyValue #1 {#1}

```

(End of definition for `\KeyValue`. This function is documented on page 355.)

**\AssignTemplateKeys** A short call to use a token register by proxy.

```

1230 \cs_new_protected:Npn \AssignTemplateKeys { \__template_assignments_pop: }

```

(End of definition for `\AssignTemplateKeys`. This function is documented on page 355.)

**\SetKnownTemplateKeys** A friendly wrapper, with some speed up for the common case of the third argument being empty.  
**\SetTemplateKeys**

```

1231 \cs_new_protected:Npn \SetKnownTemplateKeys #1#2#3
1232   {
1233     \tl_if_empty:oTF {#3}
1234     {
1235       \tl_set_eq:NN \UnusedTemplateKeys \c_empty_tl
1236     }
1237   {

```

```

1238     \keys_set_known:noN { template / #1 / #2 } {#3} \UnusedTemplateKeys
1239   }
1240 }
1241 \cs_new_protected:Npn \SetTemplateKeys #1#2#3
1242 {
1243   \tl_if_empty:oF {#3}
1244   {
1245     \keys_set:no { template / #1 / #2 } {#3}
1246   }
1247 }
1248 \tl_new:N \UnusedTemplateKeys

(End of definition for \SetKnownTemplateKeys and \SetTemplateKeys. These functions are
documented on page 356.)

### 1 Counters

This section deals with counter and other variable allocation.

1 `<*2ekernel>`

The following are from plain T<sub>E</sub>X:

`\z@` A zero dimen or number. It's more efficient to write `\parindent\z@` than `\parindent 0pt`.

`\@ne` The number 1.

`\m@ne` The number  $-1$ .

`\tw@` The number 2.

`\sxt@@n` The number 16.

`\@m` The number 1000.

`\@MM` The number 20000.

`\@xxxii` The constant 32.

2 `\chardef\@xxxii=32`

*(End of definition for \@xxxii.)*

`\@Mi` Constants 10001–10004.

`\@Mii` 3 `\mathchardef\@Mi=10001`

`\@Miii` 4 `\mathchardef\@Mii=10002`

`\@Miv` 5 `\mathchardef\@Miii=10003`

6 `\mathchardef\@Miv=10004`

*(End of definition for \@Mi and others.)*

`\@tempcnta` Scratch count registers used by L<sup>A</sup>T<sub>E</sub>X kernel commands.

`\@tempcntb` 7 `\newcount\@tempcnta`

8 `\newcount\@tempcntb`

*(End of definition for \@tempcnta and \@tempcntb.)*

`\if@tempswa` General boolean switch used by L<sup>A</sup>T<sub>E</sub>X kernel commands.

9 `\newif\if@tempswa`

*(End of definition for \if@tempswa.)*

`\@tempdima` Scratch dimen registers used by L<sup>A</sup>T<sub>E</sub>X kernel commands.

`\@tempdimb` 10 `\newdimen\@tempdima`

`\@tempdimc` 11 `\newdimen\@tempdimb`

12 `\newdimen\@tempdimc`

*(End of definition for \@tempdima, \@tempdimb, and \@tempdimc.)*

`\@tempboxa` Scratch box register used by L<sup>A</sup>T<sub>E</sub>X kernel commands.  
<sup>13</sup> `\newbox\@tempboxa`  
*(End of definition for \@tempboxa.)*

`\@tempskipa` Scratch skip registers used by L<sup>A</sup>T<sub>E</sub>X kernel commands.  
`\@tempskipb` <sup>14</sup> `\newskip\@tempskipa`  
<sup>15</sup> `\newskip\@tempskipb`  
*(End of definition for \@tempskipa and \@tempskipb.)*

`\@temptokena` Scratch token register used by L<sup>A</sup>T<sub>E</sub>X kernel commands.  
<sup>16</sup> `\newtoks\@temptokena`  
*(End of definition for \@temptokena.)*

`\@flushglue` Glue used for `\right-` & `\leftskip = 0pt plus 1fil`  
<sup>17</sup> `\newskip\@flushglue \@flushglue = 0pt plus 1fil`  
*(End of definition for \@flushglue.)*  
<sup>18</sup> `</2ekernel>`

# ltnctrl.dtx

## 1 Program control structure

This section defines a number of control structure macros, such as while-loops and for-loops.

*Historical L<sup>A</sup>T<sub>E</sub>X 2.09 comments (not necessarily accurate any more):*

```
1 \<2kernel>
2 \message{control,}
```

```
\@whilenum TEST \do {BODY}
\@whiledim TEST \do {BODY} : These implement the loop
    while TEST do BODY od
    where TEST is a TeX \ifnum or \ifdim test, respectively.
    They are optimized for the normal case of TEST initially false.
```

```
\@whilesw SWITCH \fi {BODY} : Implements the loop
    while SWITCH do BODY od
    Optimized for normal case of SWITCH initially false.
```

```
\@for NAME := LIST \do {BODY} : Assumes that LIST expands to A1,A2,
    ... ,An .
    Executes BODY n times, with NAME = Ai on the i-th iteration.
    Optimized for the normal case of n = 1. Works for n=0.
```

```
\@tfor NAME := LIST \do {BODY}
    if, before expansion, LIST = T1 ... Tn where each Ti is a
    token or {...}, then executes BODY n times, with NAME = Ti
    on the i-th iteration. Works for n=0.
```

NOTES: 1. These macros use no \@temp sequences.  
2. These macros do not work if the body contains anything that looks syntactically to TeX like an improperly balanced \if \else \fi.

```
\@whilenum TEST \do {BODY} ==
BEGIN
  if TEST
  then BODY
    \@iwhilenum{TEST \relax BODY}
END
```

```
\@iwhilenum {TEST BODY} ==

# lterror.dtx

## 1 Error handling and tracing

This section defines L<sup>A</sup>T<sub>E</sub>X's error commands.

```
1 <*2kernel>
```

The ‘2kernel’ code ensures that a `\usepackage{autoerr}` is essentially ignored if a ‘full’ format is being used that has the error messages already in the format.

These days we don't support autoloading approach any longer, but this part bit is kept in case it is used in old documents.

```
2 \expandafter\let\csname ver@autoerr.sty\endcsname\fmtversion
```

### 1.1 General commands

**\MessageBreak** This command prints a new-line inside a message, followed by a continuation line begun with `\@msg@continuation`. Normally it is defined to be `\relax`, but inside messages, it is let to `\@message@break`.

```
3 \let\MessageBreak\relax
```

*(End of definition for \MessageBreak.)*

**\GenericInfo** This takes two arguments: a continuation and a message, and sends the result to the log file.

```
4 \DeclareRobustCommand{\GenericInfo}[2]{%
5   \begingroup
6     \def\MessageBreak{^^J#1}%
7     \set@display@protect
8     \immediate\write\m@ne{#2\on@line.}%
9   \endgroup
10 }
```

*(End of definition for \GenericInfo.)*

**\GenericWarning** This takes two arguments: a continuation and a message, and sends the result to the screen.

```
11 \DeclareRobustCommand{\GenericWarning}[2]{%
12   \begingroup
13     \def\MessageBreak{^^J#1}%
14     \set@display@protect
15     \immediate\write\@unused{^^J#2\on@line.^^J}%
16   \endgroup
17 }
```

*(End of definition for \GenericWarning.)*

`\GenericError` This macro takes four arguments: a continuation, an error message, where to go for further information, and the help information. It displays the error message, and sets the error help (the result of typing `h` to the prompt), and does a horrible hack to turn the last context line (which by default is the only context line) into just three dots. This could be made more efficient.

```

18 \bgroup
19 \lccode'\@=' \ %
20 \lccode'\~=' \ %
21 \lccode'\}=' \ %
22 \lccode'\{=' \ %
23 \lccode'\T=' \T%
24 \lccode'\H=' \H%
25 \catcode'\ =11\relax%
26 \lowercase{%
27 \egroup%
```

Unfortunately T<sub>E</sub>X versions older than 3.141 have a bug which means that `^^J` does not force a linebreak in `\message` and `\errmessage` commands. So for these old T<sub>E</sub>X's we use `\typeout` to produce the message, and then have an empty `\errmessage` command. This causes an extra line of the form

.

To appear on the terminal, but if you do not like it, you can always upgrade your T<sub>E</sub>X! In order for your format to use this version, you must define the macro `\TeXversion` to be the version number, e.g., 3.14 of the underlying T<sub>E</sub>X. See the comments in `ltdircheck.dtx`.

```

28 \dimen@ifx\TeXversion\undefined4\else\TeXversion\fi\p@%
29 \ifdim\dimen@>3.14\p@%
    First the 'standard case'.

(End of definition for \GenericError.)

<pre> \PackageError \PackageWarning \PackageWarningNoLine \PackageInfo \ClassError \ClassWarning \ClassWarningNoLine \ClassInfo </pre>	<p>These commands are intended for use by package and class writers, to give information to authors. The syntax is:</p> <pre> \PackageError{&lt;package&gt;}{&lt;error&gt;}{&lt;help&gt;} \PackageWarning{&lt;package&gt;}{&lt;warning&gt;} \PackageWarningNoLine{&lt;package&gt;}{&lt;warning&gt;} \PackageInfo{&lt;package&gt;}{&lt;info&gt;} </pre>
--	--

and similarly for classes. The **Error** commands print the `<error>` message, and present the interactive prompt; if the author types `h`, then the `<help>` information is displayed. The **Warning** commands produce a warning but do not present the interactive prompt. The **WarningNoLine** commands do the same, but don't print the input line number. The **Info** commands write the message to the `log` file. Within the messages, the command `\MessageBreak` can be used to break a line, `\protect` can be used to protect command names, and `\space` is a space, for example:

```

\newcommand{\foo}{F00}
\PackageWarning{ethel}{%
  Your hovercraft is full of eels,\MessageBreak
  and \protect\foo\space is \foo}

```

produces:

```

Package ethel warning: Your hovercraft is full of eels,
(ethel)                and \foo is F00 on input line 54.

```

```

```

*(End of definition for \@spaces.)*

## 1.2 Specific errors

**\@eha** The more common error help messages.

```

\@ehb
219 \gdef\@eha{%
\@ehc
220   Your command was ignored.\MessageBreak
\@ehd
221   Type \space I <command> <return> \space to replace it %
222   with another command,\MessageBreak
223   or \space <return> \space to continue without it.}
224 \gdef\@ehb{%
225   You've lost some text. \space \@ehc}
226 \gdef\@ehc{%
227   Try typing \space <return> %

```

```

228 \space to proceed.\MessageBreak
229 If that doesn't work, type \space X <return> \space to quit.}
230 \gdef\@ehd{%
231 You're in trouble here. \space\@ehc}

(End of definition for \@eha and others.)

\@notdefinable Error message generated in \@ifdefinable from calls to one of the commands \newcommand,
\newlength or \newtheorem specifying an already-defined command name or one that
begins \end....
232 \gdef\@notdefinable{%
233 \@latex@error{%
234 Command \@backslashchar\reserved@a\space
235 already defined.\MessageBreak
236 Or name \@backslashchar\@qend... illegal,
237 see p.192 of the manual}\@eha}

(End of definition for \@notdefinable.)

\@nolnerr Generated by \newline and \\ when called in vertical mode.
238 \gdef\@nolnerr{%
239 \@latex@error{There's no line here to end}\@eha}

(End of definition for \@nolnerr.)

\@nocounterr Generated by \setcounter, \addtocounter or \newcounter if applied to an undefined
counter <cnt>.

\@nocnterr Obsolete error message generated in LATEX2.09 by \setcounter, \addtocounter or
\newcounter for undefined counter. DO NOT use for LATEX 2ε it MIGHT vanish! Use
\@nocounterr{<cnt>} instead.
240 \gdef\@nocounterr#1{%
241 \@latex@error{No counter '#1' defined}\@eha}
242 \gdef\@nocnterr{\@nocounterr?}

(End of definition for \@nocounterr and \@nocnterr.)

\@ctrerr Called when trying to print the value of a counter numbered by letters that's greater
than 26.
243 \gdef\@ctrerr{%
244 \@latex@error{Counter too large}\@ehb}

(End of definition for \@ctrerr.)

\@nodocument Error produced if paragraphs are typeset in the preamble.
245 \gdef\@nodocument{%
246 \@latex@error{Missing \protect\begin{document}}\@ehd}

(End of definition for \@nodocument.)

```

`\@badend` Called by `\end` that doesn't match its `\begin`. RmS 1992/08/24: added code to `\@badend` to display position of non-matching `\begin`. FMi 1993/01/14: missing space added.

The environment name has to literally match, i.e., what is stored in `\@currenvir` (after one expansion) must match what is passed to `\end` (without expansion). If not we complain. Not the absolute best solution but at least it avoids getting `\begin{foo}` ended by `\end{foo}` which was possible in the past.

```
247 \gdef\@badend#1{%
248   \latex@error{\protect\begin
249     {\detokenize\expandafter{\@currenvir}}\@currenvline
250     \space ended by \protect\end{\detokenize{#1}}}\@eha}
```

*(End of definition for \@badend.)*

`\@badmath` Called by `\[, \]`, `\(` or `\)` when used in wrong mode.

```
251 \gdef\@badmath{%
252   \latex@error{Bad math environment delimiter}\@eha}
```

*(End of definition for \@badmath.)*

`\@toodeep` Called by a list environment nested more than six levels deep, or an `enumerate` or `itemize` nested more than four levels.

```
253 \gdef\@toodeep{%
254   \latex@error{Too deeply nested}\@ehd}
```

*(End of definition for \@toodeep.)*

`\@badpoptabs` Called by `\endtabbing` when not enough `\poptabs` have occurred, or by `\poptabs` when too many have occurred.

```
255 \gdef\@badpoptabs{%
256   \latex@error{\protect\pushtabs\space and \protect\poptabs
257     \space don't match}\@ehd}
```

*(End of definition for \@badpoptabs.)*

`\@badtab` Called by `\>`, `\+`, `\-` or `\<` when stepping to an undefined tab.

```
258 \gdef\@badtab{%
259   \latex@error{Undefined tab position}\@ehd}
```

*(End of definition for \@badtab.)*

`\@preamerr` This error is special: it appears in places where we normally have to `\protect` expansions. However, to prevent a protection of the error message itself (which would result in the message getting printed not issued on the terminal) we need to locally reset `\protect` to `\relax`.

```
260 \gdef\@preamerr#1{%
261   \begingroup
262     \let\protect\relax
263     \latex@error{\ifcase #1 Illegal character\or
264       Missing @-exp\or Missing p-arg\fi\space
265       in array arg}\@ehd
266   \endgroup}
```

*(End of definition for \@preamerr.)*

`\@badlinearg` Occurs in `\line` and `\vector` command when a bad slope argument is encountered.

```

267 \gdef\@badlinearg{%
268   \latexerror{%
269     Bad \protect\line\space or \protect\vector
270     \space argument}\@ehb}

(End of definition for \@badlinearg.)

```

`\@LRmoderr` A command is not allowed in restricted horizontal mode, i.e., in LR-mode in L<sup>A</sup>T<sub>E</sub>X terminology.

```

271 \gdef\@LRmoderr{%
272   \latexerror{Not allowed in LR mode}\@ehb}

(End of definition for \@LRmoderr.)

```

`\@parmoderr` Occurs in a float environment or a `\marginpar` when encountered in inner vertical mode.

```

273 \gdef\@parmoderr{%
274   \latexerror{Not in outer par mode}\@ehb}

(End of definition for \@parmoderr.)

```

`\@fltovf` Occurs in float environment or `\marginpar` when there are no more free boxes for storing floats.

```

275 \gdef\@fltovf{%
276   \latexerror{Too many unprocessed floats}\@ehb}

(End of definition for \@fltovf.)

```

`\@latexbug` Occurs in output routine. This is bad news.

```

277 \gdef\@latexbug{%
278   \latexerror{This may be a LaTeX bug}{Call for help}}

(End of definition for \@latexbug.)

```

`\@badcrerr` This error was removed and replaced by `\@nolnerr`.

```

279 %\def\@badcrerr {\latexerror{Bad use of \protect\\}\@ehc}

(End of definition for \@badcrerr.)

```

`\@noitemerr` `\addvspace` or `\addpenalty` was called when not in vmode. Probably caused by a missing `\item`.

```

280 \gdef\@noitemerr{%
281   \latexerror{Something's wrong--perhaps a missing %
282     \protect\item}\@ehc}

(End of definition for \@noitemerr.)

```

`\@notprerr` A command that can be used only in the preamble appears after the command `\begin{document}`.

```

283 \gdef\@notprerr{%
284   \latexerror{Can be used only in preamble}\@eha}

(End of definition for \@notprerr.)

```

`\@inmatherr` Issued by commands that don't work correctly within math (like `\item`). There is no real error recovery happening, e.g., the user might get additional errors afterwards.

```

285 \gdef\@inmatherr#1{%
286   \relax
287   \ifmmode
288     \@latex@error{Command \protect#1 invalid in math mode}\@ehc
289   \fi}

```

*(End of definition for \@inmatherr.)*

`\@invalidchar` An error for use with invalid characters. This is commented out, since we decided to use catcode 15 instead.

```

290 %\def\@invalidchar{\@latex@error{Invalid character in input}\@ehc}

```

*(End of definition for \@invalidchar.)*

As well as the above error commands some error messages are directly coded to save space. The messages already present in L<sup>A</sup>T<sub>E</sub>X2.09 include:

**Environment --- undefined**

Issued by `\begin` for undefined environment.

**Tab overflow**

Occurs in `\=` when maximum number of tabs exceeded.

**\< in mid line**

Occurs in `\<` when it appears in middle of line.

**Float(s) lost**

In output routine, caused by a float environment or `\marginpar` occurring in inner vertical mode.

### 1.3 Tracing

The `trace` package implements the commands `\traceon` and `\traceoff` that work similar to `\tracingall` but skip certain code blocks that produce a lot of tracing output being of no interest during debugging (for example loading a font). Code blocks that should be hidden during tracing need to be surrounded by the macros `\conditionally@traceoff` and `\contionally@traceon`.

For the kernel code the `trace` package then redefines a number of macros to include this tracing support.

However, in order to allow any macro package to react to `\traceon` we also provide dummy definitions for the two commands in the kernel so that they can be used by external packages without the need to distinguish between `trace` being loaded or not.

`\conditionally@traceon` These are only dummy definitions. For details see the `trace` package.

```

\conditionally@traceoff
291 \let\conditionally@traceon\@empty
292 \let\conditionally@traceoff\@empty

```

*(End of definition for \conditionally@traceon and \conditionally@traceoff.)*

```

293 \</2kernel>

```

## File 15

# ltpar.dtx

## 1 Paragraphs

This section of the kernel declares the commands used to set `\par` and `\everypar` when ever their function needs to be changed for a long time.

This file here describes the interfaces that have been in the kernel forever, used to implement the scenarios described below. They remain valid but are now augmented in the next file (`ltpara.dtx`) to add hooks to paragraphs. At some point we will consolidate the two files further.

There are two situations in which `\par` may be changed:

- Long-term changes, in which the new value is to remain in effect until the current environment is left. The environments that change `\par` in this way are the following:
  - All list environments (itemize, quote, etc.)
  - Environments that turn `\par` into a noop: tabbing, array and tabular.
- Temporary changes, in which `\par` is restored to its previous value the next time it is executed. The following are all such uses.
  - `\end` when preceded by `\@endparenv`, which is called by `\endtrivlist`
  - The mechanism for avoiding page breaks and getting the spacing right after section heads.

### 1.1 Implementation

`\@setpar` To permit the proper interaction of these two situations, long-term changes are made by the `\@setpar{<VAL>}` command. It's function is:

To set `\par`. It `\def`'s `\par` and `\@par` to `<VAL>`.

`\@restorepar` Short-term changes are made by the usual `\def\par` commands. The original values are restored after a short-term change by the `\@restorepar` commands.

`\@@par` `\@@par` always is defined to be the original TeX `\par`.

`\everypar` `\everypar` is changed only for the short term. Whenever `\everypar` is set non-null, it should restore itself to null when executed.

The following commands change `\everypar` in this way:

- `\item`
- `\end` when preceded by `\@endparenv`, which is called by `\endtrivlist`
- `\minipage`

When dealing with `\par` and `\everypar` remember the following two warnings:

1. Commands that make short-term changes to `\par` and `\everypar` must take account of the possibility that the new commands and the ones that do the restoration may be executed inside a group. In particular, `\everypar` is executed inside a group whenever a new paragraph begins with a left brace. The `\everypar` command that restores its definition should be local to the current group (in case the command is inside a minipage used inside someplace where `\everypar` has been redefined). Thus, if `\everypar` is redefined to do an `\everypar{}` it could take several executions of `\everypar` before the restoration “holds”. This usually causes no problem. However, to prevent the extra executions from doing harm, use a global switch to keep anything harmful in the new `\everypar` from being done twice.
2. Commands that change `\everypar` should remember that `\everypar` might be supposed to set the following switches false:
  - `@nobreak`
  - `@minipage`

they should do the setting if necessary.

```

1 <*2kernel>
2 \message{par,}

```

```

\@setpar  Initiate a long-term change to \par.
\@par      3 \def\@setpar#1{\def\par{#1}\def\@par{#1}}

```

The default definition of `\@par` will ensure that if `\@restorepar` defines `\par` to execute `\@par` it will redefine itself to the primitive `\@@par` after one iteration.

```

4 \def\@par{\let\par\@@par\par}

```

*(End of definition for \@setpar and \@par.)*

```

\@restorepar  Restore from a short-term change to \par.
              5 \def\@restorepar{\def\par{\@par}}
              6 </2kernel>

```

*(End of definition for \@restorepar.)*

## File 16

# ltpara.dtx

### Abstract

This code defines four special kernel hooks to support paragraph tagging as well as four public hooks which can be occasionally useful.

## 1 Introduction

The building of paragraphs in the T<sub>E</sub>X engine(s) has a number of peculiarities that makes it on one hand fairly flexible but on the other hand somewhat awkward to control or reliably to extend. Thus to better understand the code below we start with a brief introduction of the mechanism; for more details refer to the T<sub>E</sub>Xbook [?, chap. 14] (for the full truth you may even have to study the program code).

### 1.1 The default processing done by the engine

T<sub>E</sub>X automatically starts building a paragraph when it is currently in vertical mode and encounters anything that can only live in horizontal mode. Most often this is a character, but there are also many commands that can be used only in horizontal mode. If any of them is encountered, T<sub>E</sub>X will immediately back up (i.e., the character or command is read later again), adds a `\parskip` glue to the current vertical list unless the list is empty, switches to horizontal mode, starts its special “start of paragraph processing” and only then rereads the character or command that caused the mode change.<sup>24</sup>

This “start of paragraph processing” first adds an empty box at the start of the horizontal list of width `\parindent` (which represents the paragraph indentation) unless the paragraph was started with `\noindent` in which case no such box is added<sup>25</sup>. It then reads and processes all tokens stored in the special engine token register `\everypar`. After that it reads and processes whatever has caused the paragraph to start.

Thus out of the box, T<sub>E</sub>X offers the possibility to put some special code into `\everypar` to gain control at (more or less) the start of the paragraph. For example, in LaTeX and a number of packages, special code like the following is sometimes used:

```
\everypar{\setbox\z@\lastbox}\everypar{} ...}
```

This removes the paragraph indentation box again (that was already placed by T<sub>E</sub>X), then resets `\everypar` so that it doesn’t do anything on the next paragraph start and then does whatever it wants to do, e.g., in an `\item` of a list it will typeset the label in front of the paragraph text. However, there is only one such `\everypar` token register and if different packages and/or the kernel all attempt to add their own code here, coordination is very difficult if not impossible.

The process when the paragraph ends has different mechanisms and interfaces. A paragraph ends when the engine primitive `\par` is called while T<sub>E</sub>X is in unrestricted horizontal mode, i.e., is building a paragraph. At other times this primitive does nothing or generates as an error depending on the mode T<sub>E</sub>X is in, e.g., the `\par` in `\hbox{a\par b}` is ignored, but `$a\par b$` would complain.

---

<sup>24</sup>Already not quite true: the command `\noindent` starts the paragraph but influences the special processing by suppressing the paragraph indentation box normally inserted by it.

<sup>25</sup>That’s a bit different from placing a zero-sized box!

If this primitive ends the paragraph it does some special “end of horizontal list” processing, then calls  $\text{\TeX}$ ’s paragraph builder; this breaks the horizontal list into lines and then these lines are added as boxes to the enclosing vertical list and  $\text{\TeX}$  returns to vertical mode.

This  $\text{\par}$  command can be given explicitly, but there are also situations in which  $\text{\TeX}$  is generating it on the fly. Most often this happens when  $\text{\TeX}$  encounters a blank line which is automatically changed to a  $\text{\par}$  command which is then executed. The other possibility is that  $\text{\TeX}$  encounters a command which is incompatible with horizontal processing, e.g.,  $\text{\vskip}$  (a request for adding vertical space). In such cases it silently backs up, and inserts a  $\text{\par}$  in the hope that this gets it out of horizontal mode and makes the vertical command acceptable.

The important point to note here is that  $\text{\TeX}$  really inserts the command with the name  $\text{\par}$ , which can be redefined. Thus, it may not have its original “primitive” meaning and therefore may not end the horizontal list and call the paragraph builder. This approach offers some flexibility but also allows you to easily produce a  $\text{\TeX}$  document that loops forever, for example, the simple line

```
A \let\par\relax \vskip
```

will start a horizontal list at A, redefines  $\text{\par}$ , then sees  $\text{\vskip}$  and inserts  $\text{\par}$  to end the paragraph. But this now only runs  $\text{\relax}$  so nothing changes and  $\text{\vskip}$  is read again, issues a  $\text{\par}$  which .... In short, it only takes a plain  $\text{\TeX}$  document with five tokens to run forever (since no memory is consumed and therefore eventually exhausted).

There is no way other than changing  $\text{\par}$  to gain control at the end of a paragraph, i.e., there is no token list like  $\text{\everypar}$  that is inserted. Hence the only way to change the default behavior is to modify the action that  $\text{\par}$  executes, with similar issues as outlined before: different processes need to ensure that they do not overwrite their modifications or worse, think that the  $\text{\par}$  in front of them is the engine primitive while in fact it has already been changed by other code.

To make matters slightly worse there are a few places where  $\text{\TeX}$  handles the situation differently (most likely for speed reasons back when computers were much slower). If  $\text{\TeX}$  finds itself in unrestricted horizontal mode at the end of building a vertical box (for an  $\text{\insert}$ ,  $\text{\vadjust}$  or executing the output routine code), it will finish the horizontal list not by issuing a  $\text{\par}$  command (which would be consistent with all other places) but by simply executing the primitive meaning of  $\text{\par}$ , regardless of the actual definition that  $\text{\par}$  has at the time.

Thus, if you have carefully crafted a redefined  $\text{\par}$  to execute some special actions at the end of a paragraph and you write something like

```
\vbox{Some paragraph ... text.}
```

you will find that your code does not get run for the last paragraph in that box.  $\text{\LaTeX}$  avoids this problem, by making sure that its boxes (such as  $\text{\parbox}$  or the  $\text{\minipage}$  environment, etc.) all internally add an explicit  $\text{\par}$  at the end so that such code is run and  $\text{\TeX}$  finds itself in vertical mode already without the need to start up the paragraph builder internally. But, of course, this only works for boxes under direct control of the  $\text{\LaTeX}$  kernel; if some package uses low-level  $\text{\vboxes}$  without adding this precaution the  $\text{\TeX}$  optimization kicks in and no special  $\text{\par}$  code is executed.

And there is another optimization that is painful: if a paragraph is interrupted by a mathematical display, e.g.,  $\text{\[...]}$  in  $\text{\LaTeX}$  or  $\text{\$ \$... \$ \$}$  in plain  $\text{\TeX}$ , then  $\text{\TeX}$  will resume horizontal mode afterward, i.e., it will start to build a new horizontal list

without inserting an indentation box or `\everypar` at that point. However, if that list immediately ends with an explicit or implicit `\par` then  $\text{\TeX}$  will simply throw away this “null” paragraph and not do its usual “end of horizontal list” processing, so this special case also needs to be accounted for when introducing any extended processing.

## 2 The new mechanism implemented for $\text{\LaTeX}$

To improve the situation (and also to support automatic tagging of PDF documents) we now offer public as well as private hooks at the start and end of the paragraph processing. The public hooks can be used by packages (or by the user in the preamble or within the document) and using the hook mechanisms it is possible to reorder or arrange code from different packages in such a way that these can safely coexist.

To make that happen we have to make use of the basic functionality that is offered by  $\text{\TeX}$ , e.g., we install special code inside `\everypar` to provide hooks at the beginning and we redefine `\par` to do some special processing when appropriate to install hooks at the end of the paragraph.

In order to make this work, we have to ensure that package use of `\everypar` is not overwriting our code. This is done through a trick: we basically hide the real `\everypar` from the packages and offer them a new token register (with the same name). So if they install their own code it doesn’t overwrite ours. Our code then inserts the new `\everypar` at the right place inside the process so that it looks as if it was the primitive `\everypar`.<sup>26</sup>

At the end of the paragraph it would be great if we could use a similar trick. However, due to the fact that  $\text{\TeX}$  inserts the token `\par` (that doesn’t have a defined meaning) we can’t hide “the real thing<sup>TM</sup>” and offer the package an indistinguishable alternate.

Fortunately,  $\text{\LaTeX}$  has already redefined `\par` for its own purposes. As a result there aren’t many packages that attempt to change `\par`, because without a lot of extra care that would fail miserably. But the bottom line is that, if you load a package that alters `\par` then the end of paragraph hooks are most likely not executing while that redefinition is active.<sup>27</sup>

---

<sup>26</sup>Ideally, `\everypar` wouldn’t be used at all by packages and instead they would simply write their code into the hooks now offered by the kernel. However, while this is the longterm goal and clearly an improvement (because then the packages do no longer need to worry about getting their code overwritten or needing to account for already existing code in `\everypar`), this will not happen overnight. For that reason support for this legacy method is retained.

<sup>27</sup>Similarly to the `\everypar` situation, the remedy is that such packages stop doing this and instead add their alterations into the paragraph hooks now provided.

## 2.1 The provided hooks

<hr/>	The following four public hooks are defined and executed for each paragraph:
para/before	
para/begin	
para/end	<b>para/before</b> This hook is executed after the kernel hook <code>\@kernel@before@para@before</code> (discussed below) in vertical mode immediately after $\text{\TeX}$ has contributed <code>\parskip</code> to the vertical list and before the actual paragraph processing in horizontal mode starts.
para/after	This hook should either not produce any typeset material or add only vertical material. If it starts a paragraph an error is generated. The reason is that we are in the starting process of processing a paragraph and so this would lead to endless recursion. <sup>28</sup>
	<b>para/begin</b> This hook is executed after the kernel hook <code>\@kernel@before@para@begin</code> (discussed below) in horizontal mode immediately before the indentation box is placed (if there is any, i.e., if the paragraph hasn't been started with <code>\noindent</code> ). The indentation box to be typeset is available to the hook as <code>\IndentBox</code> and its automatic placement (after the hook is executed) can be prevented through <code>\OmitIndent</code> . More precisely <code>\OmitIndent</code> voids the box. The indentation box is then typeset directly after the hook execution by something equivalent to <code>\box\IndentBox</code> followed by the current content of the token register <code>\everypar</code> that it is available to the kernel or to packages (that run some legacy code). One has to be careful not to add any code to the hook that starts its own paragraph (e.g., by adding a <code>\parbox</code> or a <code>\marginpar</code> inside) because that would call the hook inside again (as a new paragraph is started there) and thus lead to an endless recursion ending only after exhausting the available memory. This can only be done by making sure that is not executed for the inner paragraphs (or at least not recursively forever).
	<b>para/end</b> This hook is executed at the end of a paragraph when $\text{\TeX}$ is ready to return to vertical mode and after it has removed the last horizontal glue (but not any kerns) placed on the horizontal list. The code is still executed in horizontal mode so it is possible to add further horizontal material at this point, but it should not alter the mode (even a temporary exit from horizontal mode would create chaos—any attempt will cause an error message)! After the hook has ended the kernel hook <code>\@kernel@after@para@end</code> is executed and then $\text{\TeX}$ returns to vertical mode. The hook is offered as public hook, but because of the requirement to stay within horizontal mode one needs to be careful in what is placed into the hook. <sup>29</sup> This hook is implemented as a reversed hook.
	<b>para/after</b> This hook is executed directly after $\text{\TeX}$ has returned to vertical mode and after any material that migrated out of the horizontal list (e.g., from a <code>\vadjust</code> ) has processed.

<sup>28</sup>One could allow it but only if the newly started paragraph is processed without any hooks. Further—more correct spacing would be a bit of a nightmare so for now this is forbidden.

<sup>29</sup>Maybe we should guard against that, but it would be rather tricky to implement as mode changes can happen across group boundaries so one would need to keep a private stack just for that. Well, something to ponder.

This hook should either not produce any typeset material or add only vertical material. However, for this hook starting a new paragraph is not a disaster so that it isn't prevented.

This hook is implemented as a reversed hook.

Once that hook code has been processed the kernel hook `\@kernel@after@para@after` is executed as the final action of the paragraph processing.

---

```
\@kernel@before@para@before
\@kernel@after@para@after
\@kernel@before@para@begin
\@kernel@after@para@end
```

---

As already mentioned above there are also four kernel hooks that are executed at the start and end of the processing.

`\@kernel@before@para@before` For future extensions, not currently used by the kernel.

`\@kernel@after@para@after` For future extensions, not currently used by the kernel.

`\@kernel@before@para@begin` Used by the kernel to implement tagging. This hook is executed at the very beginning of a paragraph after `TEX` has switched to horizontal mode but before any indentation box got added or any `\everypar` was run.

It should not generate typeset material that could alter the position. Note that it should never leave hmode, otherwise you will end with a loop! We could guard against this, but since it is an internal kernel hook that shouldn't be touched this isn't checked.

`\@kernel@after@para@end` Used by the kernel to implement tagging. It is executed directly after the public `para/end` hook. After it there is a quick check that we are still in horizontal mode, i.e., that the public hook has not mistakenly ended horizontal mode prematurely (this is an incomplete check just testing the mode and could perhaps be improved (at the cost of speed)).

## 2.2 Altered and newly provided commands

---

```
\par
\endgraf
\para_end:
```

---

An explicit request for ending a paragraph is provided in plain `TEX` under the name `\endgraf`, which simply uses the primitive meaning (regardless of what `\par` may have as its current definition). In `LATEX` `\endgraf` (with that behavior) was originally also available.

With the new paragraph handling in `LATEX`, ending a paragraph means a bit more than just calling the engine's paragraph builder: the process also has to add any hook code for the end of a paragraph. Thus `\endgraf` was changed to provide this additional functionality (along with `\par` remaining subject to its current meaning).

The `expl3` name for this functionality is `\para_end:`.

**Note:** *The next two commands are still under discussion and may slightly change their semantics (as described in the document) and/or their names between now and the 2021 Spring release!*

<hr/> <code>\OmitIndent</code> <code>\para_omit_indent:</code> <hr/>	<p>Inside the <code>para/begin</code> hook one can use this command to suppress the indentation box at the start of the paragraph. (Technically it is possible to use this command outside the hook as well, but this should not be relied upon.) The box itself remains available for use.</p> <p>The expl3 name for the function is <code>\para_omit_indent:</code>.</p>
<hr/> <code>\IndentBox</code> <code>\g_para_indent_box</code> <hr/>	<p>The box register holding the indentation box for the paragraph is available for inspection (or changes) inside hooks. It remains available even if the <code>\OmitIndent</code> command was used; in that case it will just not be automatically placed.</p> <p>The expl3 name for the box register is <code>\g_para_indent_box</code>.</p>
<hr/> <code>\RawIndent</code> <code>\para_raw_indent:</code> <code>\RawNoindent</code> <code>\para_raw_noindent:</code> <code>\RawParEnd</code> <code>\para_raw_end:</code> <hr/>	<p><code>\RawIndent</code>    <i>hmode material</i>   <code>\RawParEnd</code>  <code>\RawNoindent</code> <i>hmode material</i>   <code>\RawParEnd</code></p> <p>The commands <code>\RawIndent</code> and <code>\RawNoindent</code> are not meant for normal paragraph building (where the result is a textual paragraph in the traditional meaning of the word), but for special cases where TeX’s low-level algorithm is used to achieve special effects, but where the result is not a “paragraph”.</p> <p>They are called “raw”, because they bypass L<sup>A</sup>T<sub>E</sub>X’s hook mechanism for paragraphs and simply invoke the low-level TeX algorithm. I.e., they are like the original TeX primitives <code>\indent</code> and <code>\noindent</code> (that is they execute no hooks other than <code>\everypar</code>) except that they can only be used in vertical mode and generate an error if found elsewhere.</p> <p>To avoid issues a paragraph started by them should always be ended by <code>\RawParEnd</code><sup>30</sup> and not by <code>\par</code> (or a blank line), because the latter will execute hooks which then have no counterpart at the beginning of the paragraph. It is the responsibility of the programmer to make sure that they are properly paired. This also means that one should not put arbitrary user content between these commands if that content could contain stray <code>\pars</code>.</p> <p>The expl3 names for the functions are <code>\para_raw_indent:</code>, <code>\para_raw_indent:</code> and <code>\para_raw_end:</code>.</p>

## 2.3 Examples

None of the examples in this section are meant for real use as they are far too simple-minded but they should give some ideas of what could be possible if a bit more care is applied.

### 2.3.1 Testing the mechanism

The idea is to output for each paragraph encountered some information: a paragraph sequence number, a level number in roman numerals, the environment in which this paragraph appears, and the line number where the start or end of the paragraph is, e.g., something like

<sup>30</sup>Technical note for those who know their *T<sub>E</sub>Xbook*: the `\RawParEnd` command invokes the original TeX engine definition of `\par` that (solely) triggers the paragraph builder in TeX when found inside unrestricted horizontal mode and does nothing in other processing modes.

```

PARA: 1-i start (document env. on input line 38)
PARA: 1-i end   (document env. on input line 38)
PARA: 2-i start (document env. on input line 40)
PARA: 3-ii start (minipage env. on input line 40)
PARA: 3-ii end   (minipage env. on input line 40)
PARA: 2-i end   (document env. on input line 41)

```

As you can see paragraph 2 starts on line 40 and ends on 41 and inside a minipage started paragraph 3 (start and end on line 40). If you run this on some document you will find that L<sup>A</sup>T<sub>E</sub>X considers more things “a paragraph” than you have probably thought.

This was generated by the following hook code:

```

\newcounter{paracnt}          % sequence counter
\newcounter{paralevel}        % level counter

```

To support paragraph nesting we need to maintain a stack of the sequence numbers. This is most easily done using `expl3` functions, so we switch over. This is not a very general implementation, just enough for what we need and a bit of L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> thrown in as well. When popping, the result gets stored in `\paracntvalue` and the `\ERROR` should never happen because it means we have tried to pop from an empty stack.

```

\ExplSyntaxOn
\seq_new:N \g_para_seq
\cs_new:Npn \ParaPush
  {\seq_gpush:No \g_para_seq {\the\value{paracnt}}}
\cs_new:Npn \ParaPop {\seq_gpop:NNF \g_para_seq \paracntvalue \ERROR }
\ExplSyntaxOff

```

At the start of the paragraph increment both sequence counter and level and also save the then current sequence number on our stack.

```

\makeatletter % because we use a few internal 2e commands
\AddToHook{para/begin}{%
  \stepcounter{paracnt}\stepcounter{paralevel}%
  \ParaPush
}

```

To display the sequence number we `\typeout` the current sequence and level number. The command `\@currenvir` gives us the current environment and `\on@line` produces a space and the current input line number.

```

\typeout{PARA: \arabic{paracnt}-\roman{paralevel} start
  (\@currenvir\space env.\on@line)}%

```

We also typeset the sequence number as a tiny red number in a box that takes up no horizontal space. This helps us seeing where L<sup>A</sup>T<sub>E</sub>X sees the start and end of the paragraphs in the document.

```

\llap{\color{red}\tiny\arabic{paracnt}\ }%
}

```

At the end of the paragraph we display sequence number and level again. The level counter has the correct value but we need to retrieve the right sequence value by popping it off the stack after which it is available in `\paracntvalue` the way we have set this up above.

```

\AddToHook{para/end}{%
  \ParaPop
  \typeout{PARA: \paracntvalue-\roman{paralevel} end \space\space
    (\@currenvir\space env.\on@line)}%
}

```

We also typeset again a tiny red number with that value, this time sticking out to the right.<sup>31</sup> We also decrement the level counter since our level has finished.

```

\rlap{\color{red}\tiny\ \paracntvalue}%
\addtocounter{paralevel}{-1}%
}
\makeatother

```

### 2.3.2 Mark the first paragraph of each `itemize`

The code for this is rather simple. We supply some code that is executed only once inside a hook at the start of each `itemize`. We explicitly change the color back and forth so that we don't introduce grouping around the paragraph.

```

\AddToHook{env/itemize/begin}{%
  \AddToHookNext{para/begin}{\color{blue}}%
  \AddToHookNext{para/end}{\color{black}}%
}

```

As a result the first paragraph of each `itemize` will appear in blue.

## 2.4 Some technical notes

The code tries hard to be transparent for package code, but of course any change means that there is a potential for breaking other code. So in section we collect a few cases that may be of importance if low-level code is dealing with paragraphs that are now behaving slightly differently. The notes are from issues we observed and will probably grow over time.

### 2.4.1 Glue items between paragraphs (found with `fancypar`)

In the past L<sup>A</sup>T<sub>E</sub>X placed two glue items between two consecutive paragraphs, e.g.,

```
text1 \par text2 \par
```

would show something like

```

\glue(\parskip) 0.0 plus 1.0
\glue(\baselineskip) 5.16669

```

but now there is another `\parskip` glue (that is always 0pt):

```

\glue(\parskip) 0.0 plus 1.0
\glue(\parskip) 0.0
\glue(\baselineskip) 5.16669

```

---

<sup>31</sup>Note that this can alter the document pagination, because a paragraph ending in a display (e.g., an equation) will get an extra line—in that case our tiny number has an effect even though it doesn't take up any space, because it paragraph is no longer empty and thus isn't dropped!

The reason is that we generate a “fake” paragraph to gain control and safely add the early hooks, but this generates an additional glue item. That item doesn’t contribute anything vertically but if somebody writes code that unravels a constructed list using `\lastbox`, `\unskip` and `\unpenalty` then the code has to remove one additional glue item or else it will fail.

## 3 The Implementation

```

1 <@=para>
2 <*2kernel | latexrelease>
3 \ExplSyntaxOn
4 <latexrelease> \NewModuleRelease{2021/06/01}{ltpara}
5 <latexrelease> {Paragraph-handling-and-hooks}

```

### 3.1 Providing hooks for paragraphs

`para/before` The public hooks. They are implemented as a paired set of hooks.

```

para/after 6 \hook_new_pair:n{para/before}{para/after}
para/begin 7 \hook_new_pair:n{para/begin}{para/end}
para/end

```

*(End of definition for `para/before` and others. These functions are documented on page 416.)*

`\@kernel@before@para@before` The corresponding kernel hooks (for tagging and future extensions).

```

8 \let \@kernel@before@para@before \@empty
9 \let \@kernel@before@para@begin \@empty
10 \let \@kernel@after@para@end \@empty
11 \let \@kernel@after@para@after \@empty

```

*(End of definition for `\@kernel@before@para@before` and others. These functions are documented on page 417.)*

`\g__para_standard_everypar_tl`

Whenever  $\text{\TeX}$  starts a paragraph it inserts first an indentation box and then executes the tokens stored in `\tex_everypar:D` (known to  $\text{\LaTeX}$  as `\everypar`). We alter this behavior slightly here, so that hooks are added into the right place. Otherwise the process change remains transparent to any legacy code for this space.

We keep the standard code to be used by `\tex_everypar:D` in a separate token list because we have to switch back and forth for error recovery and so altering `\tex_everypar:D` all the time should be a tiny bit faster.

```

12 <latexrelease> \IncludeInRelease{2023/06/01}
13 <latexrelease> { \g__para_standard_everypar_tl } { minipage~ fix }
14 \tl_new:N \g__para_standard_everypar_tl

```

Here is now its definition:

```

15 \tl_gset:Nn \g__para_standard_everypar_tl {

```

First we remove the indentation box and store it in `\g_para_indent_box`. If there was none because the paragraph was started by `\noindent` the box register will be void.

```

16 \box_gset_to_last:N \g_para_indent_box

```

This will make the newly started horizontal list empty, so if we stop it now and return to vertical mode it will be dropped by  $\text{\TeX}$ . We do that but inside a group so that any `\parshape` settings will not get lost as we need them for later.

```

17 \group_begin:
18 \tex_par:D
19 \group_end:

```

We then change `\tex_everypar:D` to generate an error so that we can detect and report if the `para/before` hook illegally changed out of vmode.

```

20 \tex_everypar:D { \msg_error:nnnn { hooks }{ para-mode }{before}{vertical} }
21 \@kernel@before@para@before
22 \hook_use:n {para/before}

```

Assuming the hooks have been well behaved it is time to return to horizontal mode and start the paragraph in earnest. We already have the indentation box saved away so we now have to restart the paragraph with an empty `\tex_everypar:D` and with `\tex_noindent:D`. And we need to make sure not to get another `\parskip` or rather (since we can't prevent that) that it is of zero size.

```

23 \group_begin:
24 \tex_everypar:D {}

```

There has been a long-standing problem with L<sup>A</sup>T<sub>E</sub>X's minipages in that invisible material at the beginning of a minipage (such as a `\color` setting) would result in `\parskip` being added in front of the first paragraph—something that is not done by T<sub>E</sub>X if a vertical list is completely empty. As this is happening on a very low-level in the engine it wasn't really possible to find out if this `\parskip` was added or if a space we see in front of the current point is legitimate. However, with the new paragraph handling we are in a better position: while we still don't know if there is such a space or not, we do know if we have just created an empty paragraph. Thus, if we now set `\parskip` to `-\parskip` the two will cancel each other if present and if the first was ignored because the vertical list was empty, then the second will be ignored too because it is still empty. Of course, we don't want to cancel always but only at the start of a minipage and that is signaled with the `@minipage` switch.

```

25 \skip_set:Nn \tex_parskip:D
26 { \if@minipage -\tex_parskip:D \else: \c_zero_skip \fi: }
27 \tex_noindent:D
28 \group_end:

```

That brings us back to the start of the horizontal list but we need to change `\tex_everypar:D` back to its normal content in case there are nested paragraphs coming up.

```

29 \tex_everypar:D{\g__para_standard_everypar_tl}

```

This is followed by executing the kernel and the public hook. The kernel hook is there to enable tagging.

```

30 \@kernel@before@para@begin
31 \hook_use:n {para/begin}

```

If we aren't in horizontal mode any longer the hooks above misbehaved.

```

32 \if_mode_horizontal: \else:
33 \msg_error:nnnn { hooks }{ para-mode }{begin}{horizontal} \fi:

```

Finally we reinsert the indentation box (unless suppressed) and then call `\everypar` the way legacy L<sup>A</sup>T<sub>E</sub>X code expects it.

However, adding the public `\everypar` is a bit tricky (see below) so we add that later, and indirectly.

```

34 \__para_handle_indent:
35 % \the \everypar % <--- done differently below
36 }

```

```

37 <latexrelease>\cs_set:Npn \__para_tmp:w #1#2#3#4#5 { }
38 <latexrelease>\tl_gput_right:Nx \g__para_standard_everypar_tl {

40 <latexrelease> \exp_not:N \toks
41 <latexrelease> \exp_after:wN \__para_tmp:w \token_to_meaning:N \everypar
42 <latexrelease> \c_space_tl
43 <latexrelease>}
44 <latexrelease>\EndIncludeInRelease
45 <latexrelease>\IncludeInRelease{2021/06/01}
46 <latexrelease> \{ \g__para_standard_everypar_tl \} {minipage~ fix}
47 <latexrelease>
48 <latexrelease>\tl_gset:Nn \g__para_standard_everypar_tl {
49 <latexrelease> \box_gset_to_last:N \g_para_indent_box
50 <latexrelease> \group_begin:
51 <latexrelease> \tex_par:D
52 <latexrelease> \group_end:
53 <latexrelease> \tex_everypar:D { \msg_error:nnnn { hooks } { para-mode } { before } { vertical } }
54 <latexrelease> \@kernel@before@para@before
55 <latexrelease> \hook_use:n { para/before }
56 <latexrelease> \group_begin:
57 <latexrelease> \tex_everypar:D {}
58 <latexrelease> \skip_zero:N \tex_parskip:D
59 <latexrelease> \tex_noindent:D
60 <latexrelease> \group_end:
61 <latexrelease> \tex_everypar:D { \g__para_standard_everypar_tl }
62 <latexrelease> \@kernel@before@para@begin
63 <latexrelease> \hook_use:n { para/begin }
64 <latexrelease> \if_mode_horizontal: \else:
65 <latexrelease> \msg_error:nnnn { hooks } { para-mode } { begin } { horizontal } \fi:
66 <latexrelease> \__para_handle_indent:
67 <latexrelease>}

```

We also have to add the `\everypar` toks register at the end. In case of rollback this is already allocated and we have to find out the correct number (hope this is correctly done)

```

68 <latexrelease>\cs_set:Npn \__para_tmp:w #1#2#3#4#5 { }
69 <latexrelease>\tl_gput_right:Nx \g__para_standard_everypar_tl {
70 <latexrelease> \exp_not:N \the
71 <latexrelease> \exp_not:N \toks
72 <latexrelease> \exp_after:wN \__para_tmp:w \token_to_meaning:N \everypar
73 <latexrelease> \c_space_tl
74 <latexrelease>}
75 <latexrelease>\EndIncludeInRelease

```

(End of definition for `\g__para_standard_everypar_tl`.)

`\tex_everypar:D` `\tex_everypar:D` then only has to execute `\g__para_standard_everypar_tl` by default.

```

76 \tex_everypar:D { \g__para_standard_everypar_tl }

```

(End of definition for `\tex_everypar:D`.)

`\everypar` Tokens inserted at the beginning of the paragraph are placed into `\everypar` inside legacy L<sup>A</sup>T<sub>E</sub>X code, e.g., by the list environments or by headings to handle `\clubpenalty`, etc.

Now this isn't any longer the primitive but simply a toks register used in the code above but to legacy L<sup>A</sup>T<sub>E</sub>X code that is transparent.

There is, however, a problem: a handful packages use exactly the same trick and replace the primitive with a token register and call the token register inside the renamed primitive. That is they assume that `\everypar` is the primitive and that it will still be called at the start of the paragraph even if renamed.

But if we have already replaced it by a token register then all they do is to give that token register a new name. Thus our code in `\tex_everypar:D` would call `\everypar` (which is now their token register) and the code that they added ends up in our token register which is then never used at all. A bit mind boggling I guess.

So what we have to do is not to call the token register `\everypar` by its name inside `\tex_everypar:D` but by using its actual register number.

```
77 \newtoks \everypar
```

After we have allocated a new toks register with the name `\everypar` the actual register number is available (briefly) inside `\allocationnumber`. So instead of `\the\everypar` we have to put `\the\toks{allocated number}` at the end of `\tex_everypar:D`.

So what remains doing is to append a few tokens to the token list `\g__para_standard_everypar_tl` which we do now. We use `x` expansion here to get the value of `\allocationnumber` in, all the other tokens should not be expanded at this point.

One important point here is to terminate the register allocation number with a real space. This space will get swallowed up when the number is read. Anything else, such as `\scan_stop:` would remain in the input and that would mean that it would interfere with `\everypar` code that attempts to scan ahead to see how the paragraph text starts.

```
78 \tl_gput_right:Nx \g__para_standard_everypar_tl {
79   \exp_not:N \the
80   \exp_not:N \toks
81   \the \allocationnumber
82   \c_space_tl
83 }
```

*(End of definition for \everypar.)*

**`\g_para_indent_box`** For managing the indentation we need to provide a public accessible box register

```
84 \box_new:N \g_para_indent_box
```

*(End of definition for \g\_para\_indent\_box. This function is documented on page 418.)*

**`\__para_handle_indent:`** Adding (typesetting) the indent box is straight forward. If it was emptied before it does nothing.

```
85 \cs_new:Npn \__para_handle_indent: {
86   \box_use_drop:N \g_para_indent_box
87 }
```

The declaration `\para_omit_indent:` (or `\OmitIndent`) changes that to do nothing.

```
88 \cs_new:Npn \para_omit_indent: {
89   \box_gclear:N \g_para_indent_box
90 }
```

*(End of definition for \\_\_para\_handle\_indent:.)*

**`\IndentBox`** The L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> names for the indentation box and for suppressing it for use in the `para/begin` hook.

**`\OmitIndent`**

```

91 \cs_set_eq:NN \IndentBox \g_para_indent_box
92 \cs_set_eq:NN \OmitIndent \para_omit_indent:

```

*(End of definition for `\IndentBox` and `\OmitIndent`. These functions are documented on page 418.)*

**`\para_end:`** Adding hooks to the end of a paragraph is similar but here we need to alter the command that is used by T<sub>E</sub>X to end horizontal mode and return to vertical mode, i.e., `\par`.

This is a bit more complicated as this command can appear anywhere either explicitly or implicitly added by T<sub>E</sub>X in certain situations:

- when using `\par` in the code or the document
- when using a blank line (which is converted to `\par`)
- when T<sub>E</sub>X finds any commands incompatible with horizontal mode it issues a `\par` and then rereads the command.

Unfortunately, T<sub>E</sub>X has some (these days) unnecessary optimizations: if a `\vbox` ends and T<sub>E</sub>X is still in horizontal mode it simply exercises the paragraph builder instead of issuing a `\par`. It is therefore necessary for L<sup>A</sup>T<sub>E</sub>X to ensure that this case doesn't happen and all boxes internally have a `\par` command at their end.

This `\par` may or may not run the “par primitive” (which is always available as `\tex_par:D` in `expl3`); it is permissible to have a changed meaning and it is in fact changed by L<sup>A</sup>T<sub>E</sub>X in various ways at various points inside `latex.ltx`. For this L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> code has the following conventions: `\@@par` and `\endgraf` both refer to the default meaning (in the past this was the `initex` primitive) while `\par` is the current meaning which maybe does something else.

We are now going to change this default meaning to instead run `\para_end:`, which ultimately executes the `initex` primitive but additionally adds our hooks when appropriate. This way the change is again transparent to the legacy L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> code.

In most cases `\para_end:` should behave exactly like the primitive and we achieve this by simply expanding it to the primitive which is available to us as `\tex_par:D`. This way we don't have to care about whether T<sub>E</sub>X just does nothing (e.g., if in vertical mode already) or generates an error, etc.

```

93 \cs_new_protected:Npn \para_end: {

```

CCC Maybe needs more explanation. TEMP NOTE: What should happen if in outer hmode with an empty hlist?

The only case we care about is when we are in horizontal mode (i.e., doing typesetting) and not also in inner mode (i.e., making paragraphs and not building an `\hbox`).

```

\bool_lazy_and:nnT
  { \mode_if_horizontal_p: }
  { \bool_not_p:n { \mode_if_inner_p: } }
{ ...

```

Since this is executed for each and every paragraph in a document we try to stay as fast as possible, so we do not use the above construct but two conditionals instead. Using low-level `\if_mode...` conditions would be even faster but has the danger to conflict with conditionals in the user hooks.

If `\para_end:` is executed while T<sub>E</sub>X is currently doing a low-level assignment the test for horizontal mode may get executed as part of the assignment. That is normally not an issue but we just found one case where it is:

```
\afterassignment\lst@vskip\@tempskipa \z@ \par
```

If T<sub>E</sub>X is in hmode while that assignment happens then the `\par` is seen in hmode because in the above case the assignment may not be finished (one should have used `\z@skip`) and the `\lst@vskip` will get inserted into the middle of the conditional. The `\lst@vskip` then changes to vmode and you get a surprising error about the `para/end` hook having changed modes even if you don't have any hook code(!): it is the inserted `\lst@vskip` that is actually causing the change of mode. This is what happened when the output routines got started while a `lstlisting` environment (that redefines `\vskip` in this way) was active. This is really faulty coding, but we try to be proactive and guard the conditional so that any scanning is first stopped, thus:

```
94 \scan_stop:
95 \mode_if_horizontal:TF {
96   \mode_if_inner:F {
```

In that case the action of the primitive would be to remove the last glue (but no kerns) from the horizontal list (constructed to form a paragraph) and then to append a penalty of 10000 and the `\parfillskip`; it then passes the whole list to the paragraph builder, which breaks it into lines and T<sub>E</sub>X then returns to vertical mode.

What we want to do is to add this hook code at the end of the horizontal list before any of the above happens. If there was a glue item at the end of the list then it should get removed before the hook code gets added so we have to arrange for this removal.

As in other similar cases, it may be best to add here a `\nobreak` in case the hook itself adds glue and thus creates a non-explicit and unwanted potential breakpoint. On the other hand (as has been argued) the code in the hook should perhaps have the responsibility for adding such a guard penalty in this case. This needs further analysis and decisions (as in emails).

In either case, good documentation of these hooks is essential, covering what the hook may or should provide and all such related considerations concerning the content.

There is not much point in checking if there was really a glue item at the end of the horizontal list, instead we simply try to remove one using `\tex_unskip:D`: if there wasn't one this will do nothing.

```
97 \tex_unskip:D
```

We then execute the public hook (which may add some final typeset material) followed by the kernel hook that we need for adding tagging support. None of this is supposed to change the mode—at the moment we make only a very simple test for this, more devious changes go unnoticed, but too bad as they will then probably backfire badly.

```
98 \hook_use:n{para/end}
99 \@kernel@after@para@end
100 \mode_if_horizontal:TF {
```

The final action (before getting to the point where `\tex_par:D` is called) is to add an extra glue item so that the primitive is prevented from removing intended glue (if there was some). If we don't do this and the horizontal list ends in several glue items we would end up removing two glue items instead of just the last one, which would be wrong. We use glue (rather than a kern) as that will be removed by the primitive.

There is however one other T<sub>E</sub>X optimization that hurts: in a sequence like this `$$ ... $$ \par` (with `\par` being the primitive) T<sub>E</sub>X will be in horizontal mode after the display, ready to receive further paragraph text, but since the `\par` follows immediately there is a “null” paragraph at the end and T<sub>E</sub>X simply throws that away. The space between `$$` and `\par` got already dropped during the display processing so the `\par` is

not removing any space and appending `\parfillskip`, instead it simply goes silently to vmode.

Now if we would have added something (to prevent glue removal) that would look to  $\TeX$  like material after the display and so we would end up with an empty paragraph just containing a penalty and `\parfillskip`.

We therefore check if the current hlist does end in glue (`\tex_lastnodetype:D` has the value 11) and if so we add a zero-length guard skip which will be removed by the following `\tex_par:D`.

```

101         \if_int_compare:w 11 = \tex_lastnodetype:D
102         \tex_hskip:D \c_zero_dim
103         \fi:

```

To run the `para/after` hook we first end the paragraph. This means that the `\tex_par:D` at the very end is unnecessary but executing it there unnecessarily is better than having code that tests for all the different mode possibilities.

```

104         \tex_par:D
105         \hook_use:n{para/after}
106         \@kernel@after@para@after
107     }

```

If we were not horizontal mode (the F case from above) then the earlier hook `para/end` must have been at fault, so we report that.

```

108         { \msg_error:nnnn { hooks }{ para-mode }{end}{horizontal} }

```

Finally close out the nested conditionals.

```

109     }
110 }

```

And then we can use the primitive to truly end the paragraph.

```

111 \tex_par:D
112 }

```

*(End of definition for `\para_end:`. This function is documented on page 417.)*

**`\para_raw_indent:`** The commands `\para_raw_indent:` and `\para_raw_noindent:` are like the primitives `\indent` and `\noindent` except that they can only be used in vertical mode.

**`\para_raw_noindent:`** To avoid issues a paragraph started by them should always be ended by `\para_raw_end:` and not by `\para_end:` or `\par` as the latter will execute hooks which then have no counterpart at the beginning of the paragraph. It is the responsibility of the programmer to make sure that they are properly paired.

**`\para_raw_end:`**

```

113 \cs_new:Npn \para_raw_indent: {
114     \mode_if_vertical:TF
115     {
116         \tex_everypar:D {
117             \box_gset_to_last:N \g_para_indent_box
118             \tex_everypar:D { \g__para_standard_everypar_tl }
119             \__para_handle_indent:
120             \the\everypar }
121     }
122     { \msg_error:nn { latex2e }{ raw-para } }
123 \tex_indent:D
124 }

```

```

125 \cs_new:Npn \para_raw_noindent: {
126   \mode_if_vertical:TF
127   {
128     \tex_everypar:D {
129       \tex_everypar:D { \g__para_standard_everypar_tl }
130       \the\everypar }
131   }
132   { \msg_error:nn { latex2e }{ raw-para } }
133   \tex_noindent:D
134 }
135 \cs_new_eq:NN \para_raw_end: \tex_par:D

```

(End of definition for `\para_raw_indent:`, `\para_raw_noindent:`, and `\para_raw_end:`. These functions are documented on page 418.)

**\RawIndent** The L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> names for starting and ending a paragraph without adding any hooks.  
**\RawNoIndent**  
**\RawParEnd**

```

136 \cs_set_eq:NN \RawIndent \para_raw_indent:
137 \cs_set_eq:NN \RawNoindent \para_raw_noindent:
138 \cs_set_eq:NN \RawParEnd \para_raw_end:

```

(End of definition for `\RawIndent`, `\RawNoIndent`, and `\RawParEnd`. These functions are documented on page 418.)

This ends the `para` module code.

```

139 \@@=

```

**\par** Having the new default definition for `\par` we also have to set it up so that it gets used.  
**\endgraf** This involves three commands: `\par`, `\@@par` (to which L<sup>A</sup>T<sub>E</sub>X resets `\par` occasionally)  
**\@@par** and `\endgraf`, which is another name for the “default” action of `\par`.

```

140 \cs_set_eq:NN \par \para_end:
141 \cs_set_eq:NN \@@par \para_end:
142 \cs_set_eq:NN \endgraf \para_end:

```

(End of definition for `\par`, `\endgraf`, and `\@@par`. These functions are documented on page 417.)

While this is not integrated properly into the format we have to redo the `\everypar` setting from the kernel, otherwise that gets lost (as it happens before that file is loaded).

```

143 \everypar{\@nodocument} %% To get an error if text appears before the \document

```

### 3.2 The error messages

This one is used when we detect that some hook code has changed the mode where it shouldn’t, e.g., by starting or ending a paragraph. The first argument is the hook name second the mode it should have stayed in but didn’t.

```

144 \msg_new:nnnn { hooks } { para-mode }
145 {
146   Illegal-mode~ change~ in~ hook~ 'para/#1'.\\
147   Hook~ code~ did~ not~ remain~ in~ #2~ mode.
148 }
149 {
150   Paragraph~ hooks~ cannot~ change~ the~ TeX~ mode~ without~ causing~
151   endless~ recursion.~ The~ hook~ code~ in~ 'para/#1'~ needs~ to~ stay~
152   in~ #2~ mode,~ but~ it~ didn't.~ Examine~ the~ hook~
153   code~ with~ \iow_char:N \ShowHook~ to~ find~ the~ issue.
154 }

```

And here is one used in the “raw” commands when they are used outside of vertical mode.

```

155 \msg_new:nnnn { latex2e } { raw-para }
156 {
157   Not~ in~ vertical~ mode.
158 }
159 {
160   Starting~ a~ paragraph~ with~ \iow_char:N \\\RawIndent~ or~
161   \iow_char:N \\\RawNoindent \\\
162   (or~ \iow_char:N \\\para_raw_indent:~ or~
163   \iow_char:N \\\para_raw_noindent:~ is~ only~ allowed \\\
164   if~ LaTeX~ is~ in~ vertical~ mode.
165 }

## File 17

# ltmeta.dtx

### Abstract

This code defines the `\DocumentMetadata` interface.

## 1 Introduction

In the past there was no dedicated location to declare settings concerning a document as a whole. Settings are placed somewhere in the preamble or with the class options or even with some package options. For some settings this can be too late, for example the pdf version can no longer be changed if a package has used code which already opened the PDF.

`\DocumentMetadata` as a new command unifies such settings in one place. It must be used before `\documentclass` but can be issued more than once there.

At the moment most of the code run by `\DocumentMetadata` is external to the format and subject to change. This includes the supported key/values.

For that reason all that happens right now in the format is to look for suitable support files and if found, to redirect the processing to them.

### 1.1 `\DocumentMetadata`

---

<code>\DocumentMetadata</code>	<code>\DocumentMetadata{&lt;key-value list&gt;}</code>
--------------------------------	--

---

The keys defined for `\DocumentMetadata` currently allow to set the PDF version, to set the PDF `/Lang`, to uncompress a PDF, to set the language and to declare a few PDF standards and some color profiles.

`\DocumentMetadata` is also used to activate the new PDF management code and it loads a number of required files for the PDF management code. As this forces the loading of the backend files, a backend which can't be detected automatically like `dvipdfmx`, must be set in the first `\DocumentMetadata` call (if there is more than one).

The full set of keys currently supported is documented in `documentmetadata-support.pdf` for now.

## 2 The Implementation

```
1 <*2ekernel | latexrelease>
```

Not needed yet but ...

```
2 %\ExplSyntaxOn
```

```
3 <latexrelease> \NewModuleRelease{2022/06/01}{ltmeta}
```

```
4 <latexrelease> {Document Metadata handling}
```

We start by making the conditionals testing for the use of `\DocumentMetadata` execute the the false branch. Then, inside `\DocumentMetadata`, we change them to select the true branch.

```
5 \let \IfDocumentMetadataTF \@secondoftwo
```

```
6 \let \IfDocumentMetadataT \@gobble
```

```

7 \let \IfDocumentMetadataF \@firstofone
8 \protected\def\DocumentMetadata{%
9   \InputIfFileExists{documentmetadata-support.ltx}%
10  {%

```

Support for \DocumentMetadata is available, so change the conditionals.

```

11     \let \IfDocumentMetadataTF \@firstoftwo
12     \let \IfDocumentMetadataT  \@firstofone
13     \let \IfDocumentMetadataF  \@gobble
14  }%

```

The above file is changing \DocumentMetadata to a suitable definition (or so we hope) so that it can be safely used several times in the preamble.

If the file can't be found we say so and carry on without it.

```

15  {%
16    \latex@error{No support files for
17                \noexpand\DocumentMetadata found}
18    {Is the 'LaTeX-lab' bundle installed?%
19    \MessageBreak
20    Without it, the declaration is ignored.}%

```

No point in trying this more than once if there are several calls in the document.

```

21    \let\DocumentMetadata\@gobble
22  }%
23  \DocumentMetadata
24 }

```

To allow package and class author to support for document links we provide also the new interface commands of the hyperref package for the creation of targets.

```

## File 18

# ltspace.dtx

## 1 Spacing

This section deals with spacing, and line- and page-breaking.

### 1.1 User Commands

`\nopagebreak` [ $\langle i \rangle$ ] :  $\langle i \rangle = 0, \dots, 4$ .  
Default argument = 4. Puts a penalty into the vertical list output as follows:  
0 : penalty = 0  
1 : penalty = `\@lowpenalty`  
2 : penalty = `\@medpenalty`  
3 : penalty = `\@highpenalty`  
4 : penalty = 10000  
`\pagebreak` [ $\langle i \rangle$ ] : same as except negatives of its penalty  
`\linebreak` [ $\langle i \rangle$ ] : analog of the above  
`\nolinebreak` [ $\langle i \rangle$ ] : analog of the above  
`\samepage` : inhibits page breaking most places by setting the following penalties to 10000:  
`\interlinepenalty`  
`\predisplaypenalty`  
`\postdisplaypenalty`  
`\interdisplaylinepenalty`  
`\@beginparpenalty`  
`\@endparpenalty`  
`\@itempenalty`  
`\@secpenalty`  
`\interfootnotelinepenalty`  
`\\` : initially defined to be `\newline`  
`\\[ $\langle length \rangle$ ]` : initially defined to be `\vspace{ $\langle length \rangle$ }\newline`  
Note: `\\*` adds a `\adjust{\penalty 10000}`  
OBSOLETE COMMANDS (which never made it into the manual):  
`\obeycr` : defines `<CR> == \\relax`  
`\restorecr` : restores `<CR>` to its usual meaning.

### 1.2 Chris' comments

There are several aspects of the handling of space in horizontal mode that are inconsistent or do not work well in some cases. These are largely concerned with ignoring the effect of space tokens that would otherwise typeset an inter-word space.

Negating the effect of such space tokens is achieved by two mechanisms:

- `\unskip` is used to remove the glue just added by a space that has already had its effect; it is sometimes invoked after an `\ifdim` test on `\lastskip` (see below);
- `\ignorespaces` is used to ignore space-tokens yet to come.

The test done on `\lastskip` is sometimes for equality with zero and sometimes for being positive. Recall also that the test is only on the natural length of the glue and that no glue cannot be distinguished from glue whose natural length is zero: to summarise, a pretty awful test. It is not clear why these tests are not all the same; I think that they should all be for equality. One place where `\unskip` is often used is just before a `\par` (which itself internally does an `\unskip`) and one bit of code (in `\@item`) even has two `\unskips` before a `\par`. These uses may be fossil code but if they are necessary, maybe `\@killglue` would be even safer.

Such removal of glue by `\unskip` may sometimes have the wrong result, removing not the glue from a space-token but other explicit glue; this is sometimes not what is intended.

A common way to prevent such removal is to add an `\hskip\z@` after the glue that should not be removed. This protects that glue against one `\unskip` with no test but not against more than one. It does work for ‘tested `\unskips`’. This is used by `\hspace*` but not by `\hspace`; this is inconsistent as the star is supposed to prevent removal only at the beginning of a line, not at the end, or in a tabular, etc.

If this reason for removing glue were the only consideration then a tested-`\unskip` and protection by `\hskip\z@` would suffice but would need to be consistently implemented.

However, the class of invisibles, commands and environments tries to be even cleverer: one of these tries to leave only one inter-word space whenever there is one before it and one after it; and it does this quite well.

But problems can arise when there is not a space-token on both sides of it; in particular, when an invisible appears at the beginning or end of a piece of text the method still leaves one space token whereas usually in these cases it should leave none.

Also, the current rules do not work well when more than one such command appears consecutively, separated by space-tokens; it leaves glue between every other invisible.

There is also a question about what these commands should do when they occur next to spaces that do not come from space tokens but, for example, from `\hspace`. Should they still produce ‘just one space’? If so, which one? It is good to note that the manual is sufficiently cautious about invisibles that we are not obliged to make anything work.

Another interesting side-road to explore is whether the space-tokens either side of an `\hspace{...}` should be ignored.

One alternative to the current algorithm that is often suggested is that all glue around the invisible should be consolidated into a space after it (usually without stating how much glue should be put there). The command `\nolinebreak` is implemented this way (and `\linebreak` should also be). This does not work correctly for the following common case:

```
... some text
\index{some-word}
some-word and more text.
```

This is optimal coding since it is normal to index a word that gets split across a page-break on its starting page. This would, on the other hand, fix another common (and documented) failure of the current system: when the invisible is the last thing in a paragraph the space before it is not removed and, worse, it is also hidden from the paragraph-ending mechanism so that an ‘empty’ line can be created at the end of the paragraph.

Another deficiency (I think) of the current system is that the following is treated as having the `\index` command between the paragraphs, which is probably not what the author intended (since there is no empty line after it).

```
\index{beginnings}
Beginnings of paragraphs ...
```

I know of no algorithm that will handle satisfactorily even all the most common cases; note that it could be that the best algorithm may be different for different invisibles since, for example, the common uses and expected behaviour of `\index`, `\marginpar`, `\linebreak`, `\pagebreak` and `\vspace` are somewhat different. [For example, is `\vspace` ever used in the middle of a paragraph?]

One method that can (and is) used to make invisible commands produce no space when used at the beginning of text is to put in some glue that is nearly enough the same as no glue or glue of zero length in all respects except for the precise test for not being exactly equal to zero; examples of such glue are `\hskip 1sp` and, possibly better but more complex, `\hskip -1sp \hskip 1sp`. However, this only works when it is known that user-supplied text is about to start.

Some similar concerns apply to the handling of space and penalties in vertical mode; there is an extra hurdle here as `\unskip` does not work on the main vertical list. The complexity of the tests done by `\addvspace` have never been explained.

The implementation of space hacks etc for vertical mode is another major area that needs further attention; my earlier experiments did not produce much improvement over the current unsatisfactory situation.

One particular problem is what happens when the following very natural coding is used (part of the problem here is that this looks like an hmode problem, but it is not):

```
... end of text.

\begin{enumerate}
  \item \label{item:xxx} Item text.
\end{enumerate}
```

### 1.3 Some immediate actions

- Fix bug in `\linebreak`.
- Fix bug in `\\*`.
- Reimplement `\\`, etc, removing extra `\adjusts` and getting better error trapping (this seems to involve a lot more tokens).
- Investigate whether `\\`, etc need to be errors in vmode; I think that they could be noops (maybe with a warning).
- Make all(?) `\unskips` include test for zero skip (rather than other tests or no test).
- Consider replacing `\hskip 1sp` by something better (here called an ‘infinitesimal’ skip).
- Look at all `\hskip\z@` (or similar) to see if they should be changed to an ‘infinitesimal’ skip.

- Resolve the inconsistency between `\hspace` and `\hspace*`.
- Remove unnecessary `\unskips`.
- Investigate and rationalise the ‘newline’ code.
- Find better algorithms for all sorts of things or, easier(?), fix T<sub>E</sub>X itself.

## 1.4 The code

*(End of definition for \@no@lnbk.)*

`\` The purpose of the new code is to fix a few bugs; however, it also attempts to optimize the following, in order of priority:

1. efficient execution of plain `\`;
2. efficient execution of `\[...]`;
3. memory use;
4. name-space use.

The changes should make no difference to the typeset output. It appears to be safe to use `\reserved@e` and `\reserved@f` here (other reserved macros are somewhat disastrous).

These changes made `\newline` even less robust than it had been, so now it is explicitly robust, like `\`.

The internal definition of the ‘normal’ definition of `\`.

```

*(End of definition for \@savsk and \@savsf.)*

`\@bsphack` `\@bsphack` and `\@esphack` used by macros such as `\index` and `\begin{@float} ... \end{@float}` that want to be invisible — i.e., not leave any extra space when used in the middle of text. Such a macro should begin with `\@bsphack` and end with `\@esphack`. The macro in question should not create any text, nor change the mode.

Before giving the current definition we give an extended definition that is currently not used (because it doesn't work as advertised:-)

These are generalised hacks which attempt to do sensible things when 'invisible commands' appear in vmode too.

They need to cope with space in both hmode (plus spacefactor) and vmode, and also cope with breaks etc. In vmode this means ensuring that any following `\addvspace`, etc sees the correct glue in `\lastskip`.

In fact, these improved versions should be used for other cases of 'whatsits, thingies etc' which should be invisible. They are only for commands, not environments (see notes on `\@Esphack`).

BTW, anyone know why the standard hacks are surrounded by `\ifmmode\else` rather than simply `\ifhmode`?

And are there any cases where saving the spacefactor is essential? I have some extensions where it is, but it does not appear to be so in the standard uses.

```
def \@bsphack{%
  \relax \ifvmode
    \@savsk \lastskip
    \ifdim \lastskip=\z@
    \else
      \vskip -\lastskip
    \fi
  \else
    \ifhmode
      \@savsk \lastskip
      \@savsf \spacefactor
    \fi
  \fi
}
```

I think that, in vmode, it is the safest to put in a `\nobreak` immediately after such things since writes, inserts etc followed by glue give valid breakpoints and, in general, it is possible to create breaks but impossible to destroy them.

```
def \@esphack{%
  \relax \ifvmode
    \nobreak
    \ifdim \@savsk=\z@
    \else
      \vskip \@savsk
    \fi
  \else
    \ifhmode
      \spacefactor \@savsf
      \ifdim \@savsk>\z@
        \ignorespaces
      \fi
    \fi
  \fi
}
```

```

\fi
\fi

```

For the moment we are going to ignore the vertical versions until they are correct.

```

126 \def\@bsphack{%
127   \relax
128   \ifhmode
129     \@savsk\lastskip
130     \@savsf\spacefactor
131   \fi}

```

(End of definition for \@bsphack.)

**\@esphack** Companion to \@bsphack. If this command is not properly paired with \@bsphack one might end up with a low-level T<sub>E</sub>X error: “BAD spacefactor”. One possible cause is calling \@bsphack in vertical mode, then doing something that gets you (sometimes) into horizontal mode and finally calling \@esphack. Even if no error is generated that is wrong, because \@esphack will then use the saved values for \@savsk and \@savsf from some earlier invocation of \@bsphack which will have nothing to do with the current situation.

```

213 <latexrelease> \ifdim\@savsk>\z@
214 <latexrelease> \ignoretrue
215 <latexrelease> \ignorespaces
216 <latexrelease> \fi
217 <latexrelease> \fi}%
218 <latexrelease>\EndIncludeInRelease
219 <*2ekernel>

```

(End of definition for \@Esphack.)

**\@vbsphack** Another variant which is useful for invisible things which should not live in vmode (this is how some people feel about marginals).

If it occurs in vmode then it enters hmode and ensures that \@savsk is nonzero so that the \ignorespaces is put in later. It is not used at present.

```

\def \@vbsphack{ %
  \relax \ifvmode
    \leavevmode
    \@savsk 1sp
    \@savsf \spacefactor
  \else
    \ifhmode
      \@savsk \lastskip
      \@savsf \spacefactor
    \fi
  \fi
}

```

(End of definition for \@vbsphack.)

## 1.5 Vertical spacing

L<sup>A</sup>T<sub>E</sub>X supports the plain T<sub>E</sub>X commands \smallskip, \medskip and \bigskip. However, it redefines them using \vspace instead of \skip.

Extra vertical space is added by the command \addvspace{<skip>}, which adds a vertical skip of <skip> to the document. The sequence \addvspace{<s1>} \addvspace{<s2>} is equivalent to \addvspace{<maximum of s1, s2>}.

\addvspace should be used only in vertical mode, and gives an error if it's not. The \addvspace command does *not* add vertical space if @minipage is true. The minipage environment uses this to inhibit the addition of extra vertical space at the beginning.

Penalties are put into the vertical list with the \addpenalty{<penalty>} command. It works properly when \addpenalty and \addvspace commands are mixed.

The @nobreak switch is set true used when in vertical mode and no page break should occur. (Right now, it is used only by the section heading commands to inhibit page breaking after a heading.)

**\@xaddvskip** Internal macro for \vspace handling the case that space has previously been added.

```

220 \def \@xaddvskip{%
221   \ifdim\lastskip<\@tempskipb
222     \vskip-\lastskip

```

```

223     \vskip\@tempskipb
224   \else
225     \ifdim\@tempskipb<\z@
226       \ifdim\lastskip<\z@
227         \else
228           \advance\@tempskipb\lastskip
229           \vskip-\lastskip
230           \vskip \@tempskipb
231         \fi
232       \fi
233     \fi}

```

(End of definition for \xaddvskip.)

**\addvspace** Add vertical space taking into account space already added, as described above.

```

## 1.6 Horizontal space (and breaks)

**\nobreakdashes** This idea is borrowed from the `amsmath` package but here we define a robust command. This command is a low-level command designed for use only before hyphens or dashes (such as `-`, `--`, or `---`).

It could probably be better implemented: it may need its own private token register and temporary command.

Setting the hyphen in a box and then unboxing it means that the normal penalty will not be added after it—and if the penalty is not there a break will not be taken (unless an explicit penalty or glue follows, thus the final `\nobreak`).

Note that even if it is not followed by a `'-`, it still leaves `vmode` and sets the spacefactor; so use it carefully!

```

453 \DeclareRobustCommand{\nobreakdashes}{%
454   \leavevmode
455   \toks@{}%
456   \def\reserved@a##1{\toks@\expandafter{\the\toks@-}%
457     \futurelet\@let@token \reserved@b}%
458   \def\reserved@b  {\ifx\@let@token -%
459     \expandafter\reserved@a
460     \else
461     \setbox\z@ \hbox{\the\toks@\nobreak}%
462     \unhbox\z@
463     \spacefactor\sfcode'\-
464     \fi}%
465   \futurelet\@let@token \reserved@b
466 }

```

(End of definition for `\nobreakdashes`.)

**\nobreakspace** This is a robust command that produces a horizontal space at which, in paragraph-mode, a line-break is not possible. We then define an active `~` to expand to it since this is the documented behaviour of `~`. One reason for introducing this is that some 8-bit input encodings have a slot for such a space and we do not want to use active characters as the L<sup>A</sup>T<sub>E</sub>X internal commands.

The braces in the definition of `~` are needed to ensure that a following space is preserved when reading to/from internal files.

We need to keep `\@xobeysp` as it is widely used; so here it is let to the non-robust command `\nobreakspace` .

The fragile version of `~` needs a brace group after `\nobreakspace` to prevent loss of spaces if it occurs in an expansion context. That's not an issue with the updated `\protected` definition, so we keep the code shorter and avoid that.

```

467 \DeclareRobustCommand{\nobreakspace}{%
468   \leavevmode\nobreak\ }

# ltlogos.dtx

## 1 Logos

Various logos are defined here.

`\TeX` The  $\mathrm{T}_{\mathrm{E}}\mathrm{X}$  logo, adjusted so that a full stop after the logo counts as ending a sentence.

```
1 <*/2ekernel>
2 \DeclareRobustCommand\TeX{T\kern-.1667em\lower.5ex\hbox{E}\kern-.125emX\@}
```

*(End of definition for \TeX.)*

`\LaTeX` The  $\mathrm{L}^{\mathrm{A}}\mathrm{T}_{\mathrm{E}}\mathrm{X}$  logo.

```
3 \DeclareRobustCommand{\LaTeX}{L\kern-.36em%
4     {\sbox\z@ T%
5         \vbox to\ht\z@{\hbox{\check@mathfonts
6             \fontsize\sf@size\z@
7             \math@fontsfalse\selectfont
8             A}%
9             \vss}%
10    }%
11    \kern-.15em%
12    \TeX}
```

*(End of definition for \LaTeX.)*

`\LaTeXe` The  $\mathrm{L}^{\mathrm{A}}\mathrm{T}_{\mathrm{E}}\mathrm{X}_{\varepsilon}$  logo as proposed by A-W designers.

```
13 \DeclareRobustCommand{\LaTeXe}{\mbox{\m@th
14     \if b\expandafter\@car\@series\@nil\boldmath\fi
15     \LaTeX\kern.15em2$_{\textstyle\varepsilon}$}}
16 </2ekernel>
```

*(End of definition for \LaTeXe.)*

## File 20

# ltfiles.dtx

## 1 File Handling

The following user commands are defined in this part:

<code>\document</code>	<code>(ie \begin{document})</code>
	Reads in the .AUX files and <code>\catcode</code> 's @ to 12.
<code>\nofiles</code>	
	Suppresses all file output by setting <code>\@files</code> false.
<code>\includeonly</code>	<code>{\NAME1, ... ,NAMEn}</code>
	Causes only parts NAME1, ... ,NAMEn to be read by their <code>\include</code> commands. Works by setting <code>partsw</code> true and setting <code>\@partlist</code> to NAME1, ... ,NAMEn.
<code>\include</code>	<code>{\NAME}</code>
	Does an <code>\input</code> NAME unless <code>\@partsw</code> is true and NAME is not in <code>\@partlist</code> . If <code>\@files</code> is true, then it directs .AUX output to NAME.AUX, including a checkpoint at the end.
<code>\input</code>	<code>{\NAME}</code>
	The same as TeX's <code>\input</code> , except it allows optional braces around the file name. In L <sup>A</sup> T <sub>E</sub> X 2 <sub>ε</sub> , it also avoids the primitive 'missing file' error, if the file can not be found.
<code>\IfFileExists</code>	<code>{\NAME}{\then}{\else}</code>
	If the file exists on the system, execute <i>then</i> otherwise execute <i>else</i> .
<code>\InputIfFileExists</code>	<code>{\NAME}{\then}{\else}</code>
	If the file exists on the system, execute <i>then</i> and input NAME otherwise execute <i>else</i> . <i>Historical L<sup>A</sup>T<sub>E</sub>X 2.09 comments (not necessarily accurate any more):</i>

```
1 <*2kernel>
2 \message{files,}
```

### VARIABLES, SWITCHES AND INTERNAL COMMANDS:

<code>\@mainaux</code>	: Output file number for main .AUX file.
<code>\@partaux</code>	: Output file number for current part's .AUX file.
<code>\@auxout</code>	: Either <code>\@mainout</code> or <code>\@partout</code> , depending on which .AUX file output goes to.
<code>\@input{foo}</code>	: If file foo exists, then <code>\input</code> 's it, otherwise types a warning message.
<code>@files</code>	: Switch – set false if no .AUX, .TOC, .IDX etc files are to be written
<code>@partsw</code>	: Set true by a <code>\includeonly</code> command.
<code>\@partlist</code>	: Set to the argument of the <code>\includeonly</code> command.
<code>\cp@FOO</code>	: The checkpoint for <code>\include</code> 'd file FOO.TEX, written by <code>\@writeckpt</code> at the end of file FOO.AUX

```

9 \</2kernel>
10 \<latexrelease>\IncludeInRelease{2020/10/01}%
11 \<latexrelease> {\document}{Added hook to load l3backend code}%
12 \<*2kernel | latexrelease>
13 \def\document{%
```

We do cancel the grouping as part of the `\begin` handling (this is now done inside `\begin` instead) so that the `env/<env>/begin` hook is not hidden inside `\begingroup ... \endgroup`.

```
14 % \endgroup
15 \UseOneTimeHook{begindocument/before}%
16 \<kernel@after@begindocument@before
```

Added hook to load l3backend code:

```
17 \<expl@sys@load@backend@@
18 \ifx\@unusedoptionlist\@empty\else
19 \<latex@warning@no@line{Unused global option(s):^^J%
20 \spaces[\@unusedoptionlist]}%
21 \fi
22 \@colht\textheight
23 \@colroom\textheight \vsize\textheight
24 \columnwidth\textwidth
25 \@clubpenalty\clubpenalty
26 \if@twocolumn
27 \advance\columnwidth -\columnsep
```

```

28     \divide\columnwidth\tw@ \hsize\columnwidth \@firstcolumntrue
29 \fi
30 \hsize\columnwidth \linewidth\hsize
31 \begingroup\@floatplacement\@dblfloatplacement
32     \makeatletter\let\@writefile\@gobbletwo

33     \global \let \@multiplelabels \relax
34     \input{\jobname.aux}%
35 \endgroup
36 \if@files
37     \immediate\openout\@mainaux\jobname.aux
38     \immediate\write\@mainaux{\relax}%
39 \fi

```

Dateline 1991/03/26: FMi added `\process@table` to support NFSS; This will also work with old lfonts if no other style defines `\process@table`. The following line forces the initialization of the math fonts.

```

40 \process@table
41 \let\glb@currsize\@empty % Force math initialization.

42 \normalsize
43 \everypar{}%

```

So that punctuation in headings is not disturbed by verbatim or other local changes to the space factor codes, save the document default here. This will be locally reset by the output routine. For special cases a class may want to define `\normalsfcodes` directly, in case that definition will be used. (This is an old bug, problem existed in L<sup>A</sup>T<sub>E</sub>X 2.0x and plain T<sub>E</sub>X.)

```

44 \ifx\normalsfcodes\@empty
45     \ifnum\sfcode'\.=\@m
46         \let\normalsfcodes\frenchspacing
47     \else
48         \let\normalsfcodes\nonfrenchspacing
49 \fi
50 \fi

```

For similar reasons also save the default language, this will be reset locally in the output routine. In particular it allows hyphenation in the page head even if the page break happens in verbatim. If this has already been set by a package, set to the value of `\language` at this point.

```

51 \ifx\document@default@language\m@ne
52     \chardef\document@default@language\language
53 \fi

```

Way back in 1991 (08/26) FMi & RmS set the `@noskipsec` switch to true in the preamble and to false here. This was done to trap lists and related text in the preamble but it does not catch everything; hence Change 1.1g was introduced.

```

54 \@noskipsecfalse

55 \let \@refundefined \relax

```

Just before disabling the preamble commands we execute the begin document hook which contains any code contributed by `\AtBeginDocument`. Also disable the gathering of the file list, if no `\listfiles` has been issued. `\AtBeginDocument` is redefined at this point so that and such commands that get into the hook do not chase their tail...

```

56 \@kernel@before@begindocument
57 \UseOneTimeHook{begindocument}%
58 \@kernel@after@begindocument

```

Most of the following assignments will be done globally in case the user adds something like `\begin{multicols}` to the document hook, i.e. starts are group in `\begin{document}`.

Since a value of exactly 0pt for `\topskip` causes `\twocolumn` to misbehave, we add this check, hoping that it will not cause any problems elsewhere.

```

59 \ifdim\topskip<1sp\global\topskip 1sp\relax\fi
60 \global\@maxdepth\maxdepth
61 \global\let\@begindocumenthook\@undefined
62 \ifx\@listfiles\@undefined
63   \global\let\@filelist\relax
64   \global\let\@addtofilelist\@gobble
65 \fi

```

At the very end we disable all preamble commands. This has to happen after the begin document hooks was executed so that this hook can still use such commands.

```

66 \gdef\do##1{\global\let ##1\@notprerr}%
67 \@preamblecmds

```

The next line saves tokens and also allows `\@nodocument` to be used directly to trap preamble errors.

```

68 \global\let \@nodocument \relax

```

The next line is a pure safety measure in case a do list is ever expanded at the wrong place. In addition it will save a few tokens to get rid of the above definition.

```

69 \global\let\do\noexpand
70 \UseOneTimeHook{begindocument/end}%

```

Use of the hook might mean that we are already in horizontal mode, so ignore the space after `\begin{document}`.

```

71 \ignorespaces

```

Provide a global definition for `\do` as well, so that it is already defined in the preamble and not late as `\begin{document}` overwriting some definition given by the unsuspecting user in the preamble.

```

72 \let\do\noexpand

```

The `begindocument` hook already existed in the kernel since 1994 under the name `\atbegindocumenthook` the additional ones are originally from the `etoolbox` package under the names `\@endpreamblehook` `\afterpreamble`.

```

73 \NewHook{begindocument}
74 \NewHook{begindocument/before}
75 \NewHook{begindocument/end}

```

Above we used two kernel only hooks to be run after the public `begindocument/before` and after `begindocument` hooks.

```

\@kernel@after@begindocument@before
\@kernel@before@begindocument
\@kernel@after@begindocument

```

In `\@kernel@after@begindocument@before` we already place one action: drop the fast execution code for the `env/document/begin` hook. That hook marks the end of the preamble and should therefore only be run once. In a normal document that is anyway the case (so the code would just sit there taking up space afterwards, which these days is rather harmless), however, in more complicated scenarios where several full documents are combined to a single document it might get applied several times with harmful effects.

We therefore explicitly drop it at this point. the coding is somewhat obscure due to the name of the macro which requires constructing.

```

76 \edef \@kernel@after@begindocument@before {%
77   \let\expandafter\noexpand\csname
78     __hook env/document/begin\endcsname
79   \noexpand\@empty}

```

These internal hooks are already declared earlier (in `ltxlpl`) so that other modules could write to them.

```

197 \@onlypreamble\document

```

*(End of definition for \document and others.)*

**\normalsfcodes** The setting of `\@empty` is just a flag. This command may be defined in a class or package file. If it is still `\@empty` at `\begin{document}` it will be defined to be `\frenchspacing` or `\nonfrenchspacing`, depending on which of those appears to be in effect at that point.

```
198 \let\normalsfcodes\@empty
```

*(End of definition for \normalsfcodes.)*

**\nofiles** Set `\@fileswfalse` which suppresses the places where L<sup>A</sup>T<sub>E</sub>X makes `\immediate` writes. The `\makeindex` and `\makeglossary` are disabled. `\protected@write` is redefined not to write to the file specified, but rather to write a blank line to the log file. This ensures that a *<whatsit>* node is still created, and so spacing is not affected by the `\nofiles` command; to ensure this more generally, the `\if@nobreak` test is needed.

```

199 \def\nofiles{%
200   \@fileswfalse
201   \typeout{No auxiliary output files.^^J}%
202   \long\def\protected@write##1##2##3%

```

`\include` In the definition of `\include`, `\def\reserved@b` changed to `\edef\reserved@b` to be consistent with the `\edef` in `\includeonly`. (Suggested by Rainer Schöpf & Frank Mittelbach. Change made 20 Jul 88.)

Changed definition of `\include` to allow space at end of file name — otherwise, typing `\include{foo }` would cause L<sup>A</sup>T<sub>E</sub>X to overwrite `foo.tex`. Change made 24 May 89, suggested by Rainer Schöpf and Frank Mittelbach

Made `\include` check for being used inside an `\include`'d file, as this will not work and cause surprising results.

```

237 </2ekernel>
238 <*2ekernel | latexrelease>
239 <latexrelease>\IncludeInRelease{2020/10/01}%
240 <latexrelease> \includeonly}{Spaces in file names}%
241 \def\include#1{\relax
242 \ifnum\@auxout=\@partaux
243 \latex@error{\string\include\space cannot be nested}\@eha
244 \else

```

Here the normalization will add `.tex` for all files, (it uses the same normalization as the hooks), so we need to remove that manually. `\@strip@tex@ext` does that.

```

245 \set@curr@file{#1}%
246 \edef\@curr@file{\@strip@tex@ext\@curr@file}%

```

For historical reasons `\@include` expects an argument delimited by a space. This is kept (though unnecessary now) to avoid errors in other packages that use `\@include` directly.

```

247 \expandafter\@include\expandafter{\@curr@file} % deliberate space
248 \fi}

```

Here in `\includeonly` we also need to strip `.tex` after normalization:

```

249 \def\includeonly#1{%
250   \@partswtrue

```

*(End of definition for \@charlb and \@charrb.)*

## 1.1 Safe Input Macros

`\@curr@file` File name handling is done by generating a csname from the provided file name (which  
`\set@curr@file` means that UTF-8 octets gets turned into strings as this is what happens if they appear in a csname due to the code in `utf8.def`). By setting `\escapechar` to -1 we ensure that we don't get a backslash in front. As a result we end up with all characters as catcode 12 (plus spaces). We then sometimes add quotes around the construct (removing any existing inner quotes). Sometimes we only remove the quotes if they have been supplied by the user. There is clearly some room for improvement.

A side effect of the new code is that we will see quotes around file name displays where there haven't been any before.

For compatibility with existing code using `{abc}.tex` or `{one.two}.png`, an initial brace group is discarded before expansion and `\string` is applied. The content of the brace group is discarded. This means that a leading space will be lost unless protected (by `{ }` or `" "` or `\space`) but filenames with a space are hopefully rare.

The definition below is from 2019 and only used during kernel bootstrapping, later on in `ltfilehook.dtx` it will get overwritten.

```

471 \def\set@curr@file#1{%
472   \begingroup
473   \escapechar\m@ne
474   \xdef\@curr@file{%
475     \expandafter\expandafter\expandafter\unquote@name
476     \expandafter\expandafter\expandafter{%
477       \expandafter\string
478       \csname\@firstofone#1\@empty\endcsname}}%
479   \endgroup
480 }

```

*(End of definition for \@curr@file and \set@curr@file.)*

`\quote@name` Quoting spaces  
`\quote@@name`  
`\unquote@name`

```

a b c      -> "a b c"
"a b c"    -> "a b c"
a" "b" "c -> "a b c"
           -> ""

```

516 <*2ekernel>
```

**\IfFileExists@** Argument #1 is \@curr@file so catcode 12 string with no quotes.

**\IfFileExists@@** The original definition picked up arguments #2 and #3 in a way that they couldn't contain unbalanced conditionals. A better implementation would have been not to pick up the arguments at all but instead use the usual \@firstoftwo and \@secondoftwo. However, that changes how # is interpreted and so we can't do that nowadays without invalidating a lot of code. Therefore the somewhat curious construction near the end.

Earlier versions used \openin here, but this led to two code paths, one in expl3 and one here. To avoid that, and as the expl3 approach works by expansion, we use that here. As we need the file name to include the path, the actual expl3 function used is not the file existence test!

```
517 </2ekernel>
518 <*2ekernel | latexrelease>

**\InputIfFileExists** Now define `\InputIfFileExists` to input #1 if it seems to exist. Immediately prior to the input, #2 is executed. If the file #1 does not exist, execute ‘#3’.

This here is a temporary definition for the kernel. The real one comes somewhat later in the file `ltxfilehook.dtx`.

```

635 \DeclareRobustCommand \InputIfFileExists[2]{%
636   \IfFileExists{#1}%
637   {%
638     \expandafter\@swaptwoargs\expandafter
639     {\@filef@und}{#2\@addtofilelist{#1}\@input}}

```

*(End of definition for \InputIfFileExists.)*

**\@swaptwoargs** Swap two arguments and return them unbraced (like `\@firstoftwo` etc).

```

640 </2ekernel>
641 <*2ekernel | latexrelease>
642 <latexrelease>\IncludeInRelease{2019/10/01}%
643 <latexrelease>  {\@swaptwoargs}{Don't lose the file name}%
644 <long\def\@swaptwoargs#1#2{#2#1}

645 </2ekernel | latexrelease>
646 <latexrelease>\EndIncludeInRelease
647 <latexrelease>\IncludeInRelease{0000/00/00}%
648 <latexrelease>  {\@swaptwoargs}{Don't lose the file name}%
649 <latexrelease>\let\@swaptwoargs\undefined
650 <latexrelease>\EndIncludeInRelease
651 <*2ekernel>

```

*(End of definition for \@swaptwoargs.)*

**\input** Input a file: if the argument is given in braces use safe input macros, otherwise use TeX’s primitive `\input` command (which is called `\@input` in L<sup>A</sup>T<sub>E</sub>X).

```

652 \def\input{\@ifnextchar\bgroup\@input\@input}

```

*(End of definition for \input.)*

`\@input` Define `\@input` (i.e., `\input`) in terms of `\InputIfFileExists`.  
Changes to `\@input`: adapt to the changes to `\@missingfileerror`.

```

653 </2ekernel>
654 <*2ekernel | latexrelease>
655 <latexrelease> \IncludeInRelease{2020/10/01}%
656 <latexrelease>           {\@input}{Change in file error handling}%
657 \def\@input#1{%
658   \InputIfFileExists{#1}{}%
659   {\filename@parse\@curr@file
660    \edef\reserved@a{\noexpand\@missingfileerror
661     {\filename@area\filename@base}%
662     {\ifx\filename@ext\relax tex\else\filename@ext\fi}}%

```

This line now just sets `\@missingfile@<part>`:

```

663   \reserved@a

```

Now here we have to use it. The file here is guaranteed to exist, because `\@missingfileerror` ensures so, but we have to use `\InputIfFileExists` because it executes the file hooks.

```

664   \edef\reserved@a{\noexpand\@input{%
665    \@missingfile@area\@missingfile@base.\@missingfile@ext}}%
666   \reserved@a}}
667 </2ekernel | latexrelease>
668 <latexrelease> \EndIncludeInRelease
669 <latexrelease> \IncludeInRelease{2019/10/01}%
670 <latexrelease>           {\@input}{Quote file names}%
671 <latexrelease>
672 <latexrelease> \def\@input#1{%
673 <latexrelease>   \InputIfFileExists{#1}{}%
674 <latexrelease>   {\filename@parse\@curr@file

688 <latexrelease>   \reserved@a}}
689 <latexrelease> \EndIncludeInRelease
690 <*2ekernel>

```

*(End of definition for \@input.)*

`\@input` Define `\@input` in terms of `\IfFileExists`. So this is a ‘safe input’ command, but the files input are not listed by `\listfiles`.

We don’t want `.aux`, `.toc` files etc be listed by `\listfiles`. However, something like `.bbl` probably should be listed and thus should be implemented not by `\@input`.

```

691 \def\@input#1{%
692   \IfFileExists{#1}{\@input\@filef@und}{\typeout{No file #1.}}

```

(End of definition for \@input.)

**\@input@** Version of \@input that does add the file to \@filelist.

```
693 \def\@input@#1{\InputIfFileExists{#1}{\typeout{No file #1.}}}
```

(End of definition for \@input@.)

**\@missingfileerror** This ‘error’ command avoids T<sub>E</sub>X’s primitive missing file loop.

Missing file error. Prompt for a new filename, offering a default extension.

Changes to \@missingfileerror: rather than trying to input the file by force, now \@missingfileerror just returns three \@missingfile@<part> and the caller macro is responsible for doing the right thing with it.

```

        \let\@addtofilelist\@gobble
    \fi}

819 \@onlypreamble\listfiles

\@dofilelist 820 \let\@dofilelist\relax

821 </2ekernel>

(End of definition for \@obsoletefile and others.)

```

## File 21

# ltoutenc.dtx

## 1 Font encodings

This section of the kernel contains commands for declaring encoding-specific commands, such as accents. It also contains the code for some of the encoding files, including `omlenc.def`, `omsenc.def`, `t1enc.def` and `ot1enc.def` files, which define the OML, OMS, T1 and OT1 encodings, and the `fontenc` package for selecting encodings.

The `fontenc` package has options for encodings, of which the last option is the default encoding. For example, to use the OT2, OT3 and T1 encodings, with T1 as the default, you say:

```
\usepackage[OT2,OT3,T1]{fontenc}
```

The standard kernel set-up loads font encoding files and selects an encoding as follows.

```
\input {omlenc.def}
\input {t1enc.def}
\input {ot1enc.def}
\input {omsenc.def}
\fontencoding{OT1}
```

Note that the files in the standard `inputenc` package depend on this behaviour of the kernel.

The syntax for declaring encoding-specific commands is:

```
\DeclareTextCommand{<command>}{<encoding>}
[<number>][<default>]{<commands>}
```

This command is like `\newcommand`, except that it defines a command which is specific to one encoding. The resulting command is always robust, even if its definition is fragile. For example, the definition of `\l` in the OT1 encoding is:

```
\DeclareTextCommand{\l}{OT1}{\@xxxii l}
```

`\DeclareTextCommand` takes the same optional arguments as `\newcommand`.

```
\ProvideTextCommand{<command>}{<encoding>}
[<number>][<default>]{<commands>}
```

This acts like `\DeclareTextCommand`, but does nothing if the command is already defined.

```
\DeclareTextSymbol{<command>}{<encoding>}{<slot>}
```

This command defines a text symbol, with a particular slot in that encoding. The commands:

```
\DeclareTextSymbol{\ss}{OT1}{25}
\DeclareTextCommand{\ss}{OT1}{\char25 }
```

have the same effect, but the `\DeclareTextSymbol` is faster.

```
\DeclareTextAccent{<command>}{<encoding>}{<slot>}
```

This command declares a text accent. The commands:

```
\DeclareTextAccent{"}{OT1}{127}
\DeclareTextCommand{"}{OT1}{\add@accent {127}}
```

have the same effect.

```
\DeclareTextComposite{<command>}
                               {<encoding>}{<argument>}{<slot>}
```

This command declares a composite letter, for example in the T1 encoding `\'a` is slot 225, which is declared by:

```
\DeclareTextComposite{\'}{T1}{a}{225}
```

The *command* will normally have been declared with `\DeclareTextAccent`, or as a one-argument `\DeclareTextCommand`.

`\DeclareTextComposite` is the most common example of using the more general declaration `\DeclareTextCompositeCommand`, which can define a composite to be an arbitrary piece of text.

```
\DeclareTextCompositeCommand{<command>}
                               {<encoding>}{<argument>}{<text>}
```

For example, in the OT1 encoding Å has a hand-crafted definition this is declared as follows

```
\DeclareTextCompositeCommand{\r}{OT1}{A}
{\leavevmode\setbox\z@\hbox{!}\dimen@ht\z@\advance\dimen@-1ex%
 \rlap{\raise.67\dimen@\hbox{\char23}}A}
```

The *command* will normally have been declared with `\DeclareTextAccent`, or as a one-argument `\DeclareTextCommand`.

The commands defined using the above declarations can be used in two ways. Normally they are used by just calling the command in the appropriate encoding, for example `\ss`. However, sometimes you may wish to use a command in an encoding where it is not defined. If the command has no arguments, then you can use it in another encoding by calling `\UseTextSymbol`:

```
\UseTextSymbol{<encoding>}{<command>}
```

For example, `\UseTextSymbol{OT1}{\ss}` has the same effect as:

```
{\fontencoding{OT1}\selectfont\ss}
```

If the command has one argument then you can use it in another encoding by calling `\UseTextAccent`:

```
\UseTextAccent{<encoding>}{<command>}{<text>}
```

For example, if the current encoding is OT2 then `\UseTextAccent{OT1}{\'}{a}` has the same effect as:

```
{\fontencoding{OT1}\selectfont\'{\fontencoding{OT2}\selectfont a}}
```

You can also declare a default definition for a text command, which will be used if the current encoding has no appropriate definition. Such use will also set the definition for this command in the current encoding to equal this default definition; this makes subsequent uses of the command much faster.

```
\DeclareTextCommandDefault{<command>}{<definition>}
```

For example, the default definition of the command `\textonequarter` (which produces the fraction  $\frac{1}{4}$ ) could be built using math mode:

```
\DeclareTextCommandDefault{\textonequarter}{\ensuremath {\frac{1}{4}}}
```

There is a matching `\Provide` command which will not override an existing default definition:

```
\ProvideTextCommandDefault{<command>}{<definition>}
```

The most common use for these commands is to use symbols from other encodings, so there are some optimizations provided:

```
\DeclareTextSymbolDefault{<command>}{<encoding>}
\DeclareTextAccentDefault{<command>}{<encoding>}
```

are short for:

```
\DeclareTextCommandDefault{<command>}
      {\UseTextSymbol{<encoding>}{<command>}}
\DeclareTextCommandDefault[1]{<command>}
      {\UseTextAccent{<encoding>}{<command>}{#1}}
```

For example, to make OT1 the default encoding for `\ss` and `\'` you say:

```
\DeclareTextSymbolDefault{\ss}{OT1}
\DeclareTextAccentDefault{\'}{OT1}
```

Note that you can use these commands on any zero- or one-argument commands declared with `\DeclareText*` or `\ProvideText*`, not just those defined using `\DeclareTextSymbol` or `\DeclareTextAccent`.

## 1.1 Removing encoding-specific commands

In some cases encoding definitions are given to provide some limited support since nothing better is available, for example, the definition for `\textdollar` in OT1 is a hack since \$ and £ actually share the same slot in this encoding. Thus if such a glyph becomes available in a different encoding (e.g., TS1) one would like to get rid of the flaky one and make the default definition point to the new encoding. In such a case defining

```
\DeclareTextSymbol{\textdollar}{TS1}{36}
\DeclareTextSymbolDefault{\textdollar}{TS1}
```

is not enough since if typesetting in OT1 L<sup>A</sup>T<sub>E</sub>X will still find the encoding specific-definition for OT1 and therefore ignore the new default. Therefore to ensure that in this case the TS1 version is used we have to remove the OT1 declaration:

```
\UndeclareTextCommand{\textdollar}{OT1}
```

Since the \$ sign is a proper glyph in the T1 encoding there is no point removing its definition and forcing L<sup>A</sup>T<sub>E</sub>X to pick up the TS1 version if typesetting in this encoding. However, assume you want to use the variant dollar sign, i.e., \$ for your dollars. In that case you have to get rid of the T1 declaration as well, e.g., the following would do that for you:

```
\UndeclareTextCommand{\textdollar}{OT1}
\UndeclareTextCommand{\textdollar}{T1}
\DeclareTextCommandDefault{\textdollar}
{\UseTextSymbol{TS1}\textdollaroldstyle}
```

## 1.2 The order of declarations

If an encoding-specific command is defined for more than one encoding, then it will execute fastest in the encoding in which it was defined last since its top-level definition will be set up to execute in that encoding without any overhead.

For this reason the file `fonttext.ltx` currently first loads the definitions for the T1 encoding and then those for the OT1 encoding so that typesetting in OT1 is optimized since that is (still) the default. However, when T1 is explicitly requested (via `\usepackage[T1]{fontenc}`) the top-level definitions are automatically changed to favour T1 since its declarations are reloaded in the process.

For the same reason default declarations should never come last since they are implemented as a special encoding themselves (with the name ?). Specifying them last would simply mean to make those encoding-specific commands equally inefficient in all encodings. Therefore the `textcomp` package, for example, first sets up all defaults to point to TS1 and then declares the commands in the TS1 encoding.

## 1.3 Docstrip modules

This `.dtx` file is be used to generate several related files containing font encoding definitions. The mutually exclusive docstrip options are listed here.

T1	generates <code>t1enc.def</code> for the Cork encoding.
TS1	generates <code>ts1enc.def</code> for the Text Companion encoding.
TS1sty	generates <code>textcomp.sty</code> , package that sets up use of the Text Companion encoding.
OT1	generates <code>ot1enc.def</code> for Knuth's CM encoding.
OMS	generates <code>omsenc.def</code> for Knuth's math symbol encoding.
OML	generates <code>omlenc.def</code> for Knuth's math letters encoding.
OT4	generates <code>ot4enc.def</code> for the Polish extension to the OT1 encoding, created by B. Jackowski and M. Ryćko for use with the Polish version of Computer Modern and Computer Concrete.
TU	generates <code>tuenc.def</code> for Unicode font encoding.
package	generates <code>fontenc.sty</code> for selecting encodings.
2ekernel	for the kernel commands.

## 1.4 Definitions for the kernel

### 1.4.1 Declaration commands

This section contains definitions for commands such as accents which depend on the current encoding. These commands will usually be kept in .def files, for example `ot1enc.def` contains the definitions for the OT1 encoding.

```
1 <*2ekernel>
2 \message{font encodings,}
```

Far too many macros in one block here!

\DeclareTextCommand If you say:

\ProvideTextCommand \DeclareTextCommand{\foo}{T1}...

\DeclareTextSymbol

\@dec@text@cmd

\chardef@text@cmd

\@changed@cmd

\@changed@x

\TextSymbolUnavailable

\@inmathwarn

then `\foo` is defined to be `\T1-cmd \foo \T1\foo`, where `\T1\foo` is *one* control sequence, not two! We then call `\newcommand` to define `\T1\foo`.

```
3 \def\DeclareTextCommand{%
4   \@dec@text@cmd\newcommand}
5 \def\ProvideTextCommand{%
6   \@dec@text@cmd\providecommand}
7 \def\@enc@info#1{%
8   \GenericInfo{(Encoding)\@spaces\@spaces\@spaces\space\space}%
9   {LaTeX Encoding Info: \space\space\space#1}}%
10 \def\@dec@text@cmd#1#2#3{%
```

For logging, there are a number of different cases to cater for.

```
11 \ifcsname #3\string#2\endcsname
12 \@enc@info{%
13   \ifx#1\providecommand
14     Ignoring declaration for
15   \else
16     Redeclaring
17   \fi
18   text
```

This test distinguishes between commands and symbols:

```
19 \ifx#1\chardef@text@cmd
20   symbol
21 \else
22   command
23 \fi
24 \string#2 (encoding #3)}%
25 \fi
26 \expandafter\def\expandafter#2%
27   \expandafter{%
28     \csname#3-cmd\expandafter\endcsname
29     \expandafter#2%
30     \csname#3\string#2\endcsname
31   }%
32 \let\@ifdefinable\@rc@ifdefinable
33 \expandafter#1\csname#3\string#2\endcsname}
```

This command was introduced to fix a major bug in `\@dec@text@cmd` without changing that command itself. This was thought to be necessary because it is defined in more than one package. (Perhaps the more serious bug is to put complex low-level commands like this in packages?)

The problem it solves is that whereas both `\newcommand` and `\providecommand` (used just above) both handle the resetting of `\@ifdefinable` (following its disabling in `\@dec@text@cmd`), the primitive `\chardef` neither needs the disabling, nor does the resetting.

```

34 \def\chardef@text@cmd{%
35   \let\@ifdefinable\@ifdefinable
36   \chardef
37 }
38 \def\DeclareTextSymbol#1#2#3{%
39   \@dec@text@cmd\chardef@text@cmd#1{#2}#3\relax
40 }
```

The declarations are only available before `\begin{document}`.

```

41 \@onlypreamble\DeclareTextCommand
42 \@onlypreamble\DeclareTextSymbol
```

The sneaky bit in all this is what `\T1-cmd \foo \T1\foo` does. There are five possibilities, depending on the current values of `\protect`, `\cf@encoding` and `\ifmmode`:

- If `\protect` is `\@typeset@protect` and `\cf@encoding` is `T1`, then we execute `\T1\foo`. This should be the normal behaviour, and is optimized for speed.
- If `\protect` is `\@typeset@protect`, `\cf@encoding` is (say) `OT1`, and `\OT1\foo` is defined, then we execute `\OT1\foo`.
- If `\protect` is `\@typeset@protect`, `\cf@encoding` is (say) `OT1`, we're in text mode, and `\OT1\foo` is undefined, then we define `\OT1\foo` to be the default value of `\foo`, and execute `\OT1\foo`.
- If `\protect` is `\@typeset@protect`, `\cf@encoding` is (say) `OT1`, we're in math mode, and `\OT1\foo` is undefined, then we execute the default value of `\foo`. (This is necessary so that things like `$X_{copyright}` work properly.)
- If `\protect` is not `\@typeset@protect` then we execute `\noexpand\foo`. For example, if we are writing to a file, then this results in `\foo` being written. If we are in a `\mark`, then `\foo` will be put in the mark—since `\foo` is robust, it will then survive all the things which may happen to it whilst it's a `\mark`.

So after all that, we will either execute the appropriate definition of `\foo` for the current encoding, or we will execute `\noexpand\foo`.

The default value of `\foo` is `\?\foo` if it is defined, and an error message otherwise.

When the encoding is changed from `T1` to `OT1`, `\T1-cmd` is defined to be `\@changed@cmd` and `\OT1-cmd` is defined to be `\@current@cmd`. This means that the test for what the current encoding is can be performed quickly.

```

43 \def\@current@cmd#1{%
44   \ifx\protect\@typeset@protect
45     \inmathwarn#1%
46   \else
47     \noexpand#1\expandafter\@gobble
48   \fi}
```

```

49 \def\@changed@cmd#1#2{%
50   \ifx\protect\@typeset@protect
51     \@inmathwarn#1%
52     \expandafter\ifx\csname\cf@encoding\string#1\endcsname\relax
53       \expandafter\ifx\csname ?\string#1\endcsname\relax
54         \expandafter\def\csname ?\string#1\endcsname{%
55           \TextSymbolUnavailable#1%
56         }%
57       \fi
58       \global\expandafter\let
59         \csname\cf@encoding\string#1\expandafter\endcsname
60         \csname ?\string#1\endcsname
61       \fi
62       \csname\cf@encoding\string#1%
63         \expandafter\endcsname
64     \else
65       \noexpand#1%
66     \fi}

67 \gdef\TextSymbolUnavailable#1{%
68   \@latex@error{%
69     Command \protect#1 unavailable in encoding \cf@encoding%
70   }\@eha}

```

The command `\@inmathwarn` produces a warning message if we are currently in math mode. Note that since this command is used inside text commands, it can't call `\relax` before the `\ifmmode`. This means that it is possible for the warning to fail to be issued at the beginning of a row of an `halign` whose template enters math mode. This is probably a bad feature, but there's not much that can be done about it, since adding a `\relax` would break ligatures and kerning between text symbols.

A more efficient solution would be to make `\@inmathwarn` and `\@inmatherr` equal to `\@empty` and `\relax` by default, and to have `\everymath` reset them to their usual definitions. This is left for future investigation (for example it may break some third party code).

```

71 \def\@inmathwarn#1{%
72   \ifmmode
73     \@latex@warning{Command \protect#1 invalid in math mode}%
74   \fi}

```

(End of definition for `\DeclareTextCommand` and others.)

`\DeclareTextCommandDefault`  
`\ProvideTextCommandDefault`

These define commands with encoding ?.

Note that `\DeclareTextCommandDefault` can only be used in the preamble, but that the `\Provide` version is allowed in inputenc .def files, so is allowed anywhere.

```

75 \def\DeclareTextCommandDefault#1{%
76   \DeclareTextCommand#1?}

77 \def\ProvideTextCommandDefault#1{%
78   \ProvideTextCommand#1?}

79 \@onlypreamble\DeclareTextCommandDefault
80 %\@onlypreamble\ProvideTextCommandDefault

```

They require `\? -cmd` to be initialized as `\@changed@cmd`.

```

81 \expandafter\let\csname?\-cmd\endcsname\@changed@cmd

```

(End of definition for `\DeclareTextCommandDefault` and `\ProvideTextCommandDefault`.)

`\DeclareTextAccent` This is just a disguise for defining a T<sub>E</sub>X `\accent` command.

```
82 \def\DeclareTextAccent#1#2#3{%  
83   \DeclareTextCommand#1{#2}{\add@accent{#3}}}  
84 \@onlypreamble\DeclareTextAccent
```

(End of definition for `\DeclareTextAccent`.)

`\add@accent` To save space this code is shared between all text accents that are set using the `\accent` primitive. The argument is pre-set in a box so that any font loading that is needed is already done within the box. This is needed because font-loading involves grouping and that would prevent the accent mechanism from working so that the accent would not be positioned over the argument. Declarations that change the font should be allowed (only low-level ones are at present) inside the argument of an accent command, but not size changes, as they involve `\setbox` operations which also inhibit the mechanism of the `\accent` primitive.

Note that the whole process is within a group. For a detailed discussion of this reimplementaion and its deficiencies, see pr/3160.

```
85 \def\add@accent#1#2{\hmode@bgroup
```

Turn off the group in `\UseTextSymbol` in case this is used inside the argument of `\add@accent`.

```
86   \let\hmode@start@before@group\@firstofone  
87   \setbox\@tempboxa\hbox{#2%
```

When presetting the argument in a box we record its `\spacefactor` for later use after the accent got typeset. This way something like `\A` gets the spacefactor of `A` (i.e., 999) rather than the default value of 1000.

```
88     \global\mathchardef\accent@spacefactor\spacefactor}%
```

The accent primitive doesn't allow things `\begingroup` to interfere between accent and base character. Therefore we need to avoid that (they are some hidden inside `\maybe@load@fontshape`). As we don't have to load the fontshape in this case (as that already happened in the box above, if necessary), we simply disable that part of the code temporarily. We also ignore `\ignorespaces` which has the same issue and may show up as part of `\normalfont` if that is used.

```
89   \let\maybe@load@fontshape\relax  
90   \let\ignorespaces\relax  
91   \accent#1 #2\egroup\ifmmode\else\spacefactor\accent@spacefactor\fi}
```

Default definition for `\accent@spacefactor` prevents a horrible death of the above macro inside an unprotected `\edef`.

```
92 \let\accent@spacefactor\relax
```

(End of definition for `\add@accent`.)

`\hmode@bgroup`

```
93 \def\hmode@bgroup{\leavevmode\bgroup}
```

(End of definition for `\hmode@bgroup`.)

`\DeclareTextCompositeCommand` Another amusing game to play with `\expandafter`, `\csname`, and `\string`. When you say `\DeclareTextCompositeCommand{\foo}{T1}{a}{bar}`, we look to see if the expansion of `\T1\foo` begins with `\@text@composite`, and if it doesn't, we redefine `\T1\foo` to be:

```

\DeclareTextComposite
  \@text@composite
  \@text@composite@x
    \@strip@args
      #1 -> \@text@composite \T1\foo #1\@empty \@text@composite {...}

```

where ... is the previous definition of `\T1\foo`. Finally, we define `\T1\foo-a` to expand to `bar`.

```

141 <latexrelease>\EndIncludeInRelease
142 <*2ekernel>

143 \@onlypreamble\DeclareTextCompositeCommand

```

This all works because:

```
\@text@composite \T1\foo A\@empty \@text@composite {...}
```

expands to `\T1\foo-A` if `\T1\foo-A` has been defined, and `{...}` otherwise.

Note that `\@text@composite` grabs the first token of the argument and puts just that in the `\csname`. This is so that `\'\{\textit{e}\}` will work—it checks whether `\T1\'-\textit` is defined (which presumably it isn't) and so expands to `\{accent 1 \textit{e}\}`.

This trick won't always work, for example `\'\{\itshape e\}` will expand to (with spaces added for clarity):

```
\csname \string \T1\' - \string {\itshape e} \@empty \endcsname
```

which will die pretty horribly. Unfortunately there's not much can be done about this if we're going to use `\csname` lookups as a fast way of accessing composites.

This has an unfortunate 'misfeature' though, which is that in the T1 encoding, `\'\{aa\}` produces á. This is not the expected behaviour, and should perhaps be fixed if the fix doesn't affect performance too badly.

Finally, it's worth noting that the `\@empty` is used in `\@text@composite` so that accents will work even when the argument is empty. If you say `\'\{ }` then this looks up `\T1\'-\@empty`, which ought to be `\relax`, and so all is well. If we didn't include the `\@empty`, then `\'\{ }` would expand to:

```
\csname \string \T1\' - \string \endcsname
```

so the `\endcsname` would be `\string'ed` and the whole of the rest of the document would be put inside the `\csname`. This would not be good.

```

144 \def\@text@composite#1#2#3\@text@composite{%
145   \expandafter\@text@composite@x
146   \csname\string#1-\string#2\endcsname}

```

Originally the `\@text@composite@x` macro had two arguments and if `#1` was not `\relax` it was executed, otherwise `#2` was executed. All this happened within the `\ifx` code so that neither `#1` nor `#2` could have picked up any additional arguments from the input stream. This has now been changed using the typical `\@firstoftwo / \@secondoftwo` coding. This way the final expansion will happen without any `\else` or `\fi` intervening in the case that we need to get a further token from the input stream.

```

147 \def\@text@composite@x#1{%
148   \ifx#1\relax
149     \expandafter\@secondoftwo
150   \else
151     \expandafter\@firstoftwo
152   \fi
153   #1}

```

The command `\DeclareTextComposite` uses `\DeclareTextCompositeCommand` to declare a command which expands out to a single glyph.

```

154 \catcode\z@=11\relax
155 \def\DeclareTextComposite#1#2#3#4{%
156   \def\reserved@a{\DeclareTextCompositeCommand#1{#2}{#3}}%
157   \bgroup
158     \lccode\z@#4%
159     \lowercase{%
160       \egroup
161       \reserved@a ^~@}}
162 \catcode\z@=15\relax
163 \@onlypreamble\DeclareTextComposite

```

(End of definition for `\DeclareTextCompositeCommand` and others.)

```

164 </2ekernel>
165 <*2ekernel | latexrelease>
166 <latexrelease>\IncludeInRelease{2019/10/01}%
167 <latexrelease>          {\UseTextAccent}{Make commands robust}%

```

`\UseTextAccent` These fragile commands access glyphs from different encodings. They use grotty low-level calls to the font selection scheme for speed, and in order to make sure that `\UseTextSymbol` doesn't do anything which you're not allowed to do between an `\accent` and its glyph.

`\UseTextSymbol`

`\@use@text@encoding`

For a detailed discussion of this reimplementaion and its deficiencies, see pr/3160.

```

168 \DeclareRobustCommand*\UseTextAccent[3]{%
169   \hmode@start@before@group
170   {%

```

Turn off the group in `\UseTextSymbol` in case this is used inside the arguments of `\UseTextAccent`.

```

171     \let\hmode@start@before@group\@firstofone

193 <latexrelease>\EndIncludeInRelease
194 <*2kernel>

```

Switch to a different text encoding without any grouping for use in `\UseTextAccent` or `\UseTextSymbol` (and for `\oldstylenums`).

```

195 \def\@use@text@encoding#1{%
196   \edef\f@encoding{#1}%
197   \xdef\font@name{%
198     \csname\curr@fontshape/\f@size\endcsname}%
199   \pickup@font
200   \font@name
201   \@enc@update}

```

*(End of definition for \UseTextAccent, \UseTextSymbol, and \@use@text@encoding.)*

`\hmode@start@before@group` The `\hmode@start@before@group` starts `hmode` and should be immediately followed by an explicit `{...}`. Its purpose is to ensure that `hmode` is started before this group is opened. Inside `\add@accent` and `\UseTextAccent` it is redefined to remove this group so that it doesn't conflict with the `\accent` primitive.

For a detailed discussion see pr/3160.

```

202 \let\hmode@start@before@group\leavevmode

```

*(End of definition for \hmode@start@before@group.)*

`\DeclareTextSymbolDefault` Some syntactic sugar. Again, these should probably be optimized for speed.  
`\DeclareTextAccentDefault`

```

203 \def\DeclareTextSymbolDefault#1#2{%
204   \DeclareTextCommandDefault#1{\UseTextSymbol{#2}#1}}
205 \def\DeclareTextAccentDefault#1#2{%
206   \DeclareTextCommandDefault#1{\UseTextAccent{#2}#1}}
207 \@onlypreamble\DeclareTextSymbolDefault
208 \@onlypreamble\DeclareTextAccentDefault

```

*(End of definition for \DeclareTextSymbolDefault and \DeclareTextAccentDefault.)*

`\UndeclareTextCommand` This command safely removes an encoding specific declaration for a given encoding. It is helpful if one intends to use the default definition always and therefore wants to get rid of a declaration for some specific encoding.

```

209 \def\UndeclareTextCommand#1#2{%

```

If there is no declaration for the current encoding do nothing.

```

210   \ifcsname #2\string#1\endcsname

```

Else: throw away that declaration.

```

211     \@enc@info{Undeclare text command \string#1 (encoding #2)}%
212     \global\expandafter\let\csname#2\string#1\endcsname
213     \undefined

```

But this is unfortunately not enough, we have to take a look at the top-level definition of the encoding specific command which for a command `\foo` would look similar to `\T1-cmd \foo \T1\foo` (three tokens).

Of course, instead of `T1` one could see a different encoding name; which one depends the encoding for which `\foo` was declared last.

Now assume we have just removed the declaration for `\foo` in `T1` and the top-level of `\foo` expands to the above. Then we better change that pretty fast otherwise we do get an “undefined csname error” when we try to typeset `\foo` within `T1` instead of getting the default definition for `\foo`. And what is the best way to change that top-level definition? Well, the only “encoding” we know for sure will still be around is the default encoding denoted by `?`.

Thus in case the last token of the top-level expansion is now undefined we change the declaration to look like `\?-cmd \foo \?\foo` which is done by the following (readable?) code:

```

214     \expandafter\expandafter\expandafter
215     \ifx\expandafter\@thirdofthree#1\@undefined
216     \expandafter\gdef\expandafter#1\expandafter
217         {\csname ?-cmd\expandafter\endcsname\expandafter
218          #1\csname?\string#1\endcsname}%
219     \fi
220 \else
221
222     \@enc@info{Text command \string#1 (encoding #2) is not declared}%
223 \fi
224 }
225 \onlypreamble\UndeclareTextCommand

```

*(End of definition for \UndeclareTextCommand.)*

### 1.4.2 Hyphenation

<code>\patterns</code> <code>\@patterns</code> <code>\hyphenation</code> <code>\@hyphenation</code>	<p>We redefine <code>\patterns</code> and <code>\hyphenation</code> to allow the use of commands declared with <code>\DeclareText*</code> to be used inside them.</p> <pre> 225 %\let\@patterns\patterns 226 %\let\@hyphenation\hyphenation 227 %\def\patterns{% 228 %   \bgroup 229 %   \let\protect\@empty 230 %   \let\@typeset@protect\@empty 231 %   \let\@changed@x\@changed@x@mouth 232 %   \afterassignment\egroup 233 %   \@patterns 234 %} 235 %\def\hyphenation{% 236 %   \bgroup 237 %   \let\protect\@empty 238 %   \let\@typeset@protect\@empty 239 %   \let\@changed@x\@changed@x@mouth 240 %   \afterassignment\egroup 241 %   \@hyphenation 242 %} </pre>
--	--

*(End of definition for \patterns and others.)*

### 1.4.3 Miscellanea

`\a` The `\a` command is used to access the accent commands even when they have been redefined (for example by the `tabbing` environment). Its internal name is `\@tabacckludge`.

The `\string` within the `\csname` guards against something like `'` being active at the point of use.

```
243 \def\@tabacckludge#1{\expandafter\@changed@cmd
244                               \csname\string#1\endcsname\relax}
245 \let\a=\@tabacckludge
```

*(End of definition for \a.)*

### 1.4.4 Default encodings

We define the default encodings for most commands to be either OT1, OML or OMS. These defaults are in the kernel and therefore fonts with these encodings must be available unless these defaults are redefined elsewhere. Recall that the standard kernel loads the encoding files for these encodings, and also that for the T1 encoding.

The naming conventions in the kernel are not what we would use if we were starting from scratch... Those defined by DEK (like `\ae` and `\ss`) or by the T<sub>E</sub>X Users Group Technical Working Group on multi-lingual typesetting (like `\th` and `\ng`) have short names. Those which were added to the kernel in 1993 and early 1994 are named after their Adobe glyph names (like `\guillemotleft` and `\quotedblbase`). Unfortunately, this naming scheme won't work for all glyphs, since some names (like `\space`) are already used, and some (like `\endash`) are very likely to be defined by users. So we're now using the naming scheme of `\text` followed by the Adobe name, (like `\textendash` and `\textsterling`). Except that some glyphs don't have Adobe names, so we're using the names used by fontinst for those (like `\textcompwordmark`). Sigh.

Some accents from OT1:

```
246 \DeclareTextAccentDefault{"}{OT1}
247 \DeclareTextAccentDefault{'}{OT1}
248 \DeclareTextAccentDefault{.}{OT1}
249 \DeclareTextAccentDefault{=}{OT1}
250 \DeclareTextAccentDefault{H}{OT1}
251 \DeclareTextAccentDefault{^}{OT1}
252 \DeclareTextAccentDefault{'}{OT1}
253 \DeclareTextAccentDefault{b}{OT1}
254 \DeclareTextAccentDefault{c}{OT1}
255 \DeclareTextAccentDefault{d}{OT1}
256 \DeclareTextAccentDefault{r}{OT1}
257 \DeclareTextAccentDefault{u}{OT1}
258 \DeclareTextAccentDefault{v}{OT1}
259 \DeclareTextAccentDefault{~}{OT1}
```

Some symbols from OT1:

```
260 %\DeclareTextSymbolDefault{AA}{OT1}
261 \DeclareTextSymbolDefault{AE}{OT1}

281 \DeclareTextSymbolDefault{\textquestiondown}{OT1}
282 \DeclareTextSymbolDefault{\textquotedblleft}{OT1}
283 \DeclareTextSymbolDefault{\textquotedblright}{OT1}
284 \DeclareTextSymbolDefault{\textquoteleft}{OT1}
285 \DeclareTextSymbolDefault{\textquoteright}{OT1}
286 \DeclareTextSymbolDefault{\textsterling}{OT1}

```

Some symbols from OMS:

```

287 \DeclareTextSymbolDefault{\textasteriskcentered}{OMS}
288 \DeclareTextSymbolDefault{\textbackslash}{OMS}
289 \DeclareTextSymbolDefault{\textbar}{OMS}
290 \DeclareTextSymbolDefault{\textbardbl}{OMS}
291 \DeclareTextSymbolDefault{\textbraceleft}{OMS}
292 \DeclareTextSymbolDefault{\textbraceright}{OMS}
293 \DeclareTextSymbolDefault{\textbullet}{OMS}
294 \DeclareTextSymbolDefault{\textdaggerdbl}{OMS}
295 \DeclareTextSymbolDefault{\textdagger}{OMS}
296 \DeclareTextSymbolDefault{\textparagraph}{OMS}
297 \DeclareTextSymbolDefault{\textperiodcentered}{OMS}
298 \DeclareTextSymbolDefault{\textsection}{OMS}
299 \DeclareTextAccentDefault{\textcircled}{OMS}

```

Some symbols from OML:

```

300 \DeclareTextSymbolDefault{\textless}{OML}
301 \DeclareTextSymbolDefault{\textgreater}{OML}
302 \DeclareTextAccentDefault{\t}{OML}

```

Some defaults we can fake.

The interface for defining `\copyright` changed, it used to use `\expandafter` to add braces at the appropriate points.

```

303 \DeclareTextCommandDefault{\textcopyright}{\textcircled{c}}
304 % \expandafter\def\expandafter
305 % \copyright\expandafter{\expandafter\copyright}
306 \DeclareTextCommandDefault{\textasciicircum}{\~{}}
307 \DeclareTextCommandDefault{\textasciitilde}{\~{}}
308 \DeclareTextCommandDefault{\textunderscore}{%
309 \leavevmode \kern.06em\vbox{\hrule\@width.3em}}

```

There is no good reason anymore to fake `\textcompwordmark`.

```

310 %\DeclareTextCommandDefault{\textcompwordmark}{\leavevmode\kern\z@}
311 \DeclareTextSymbolDefault{\textcompwordmark}{T1}

```

```

312 \DeclareTextCommandDefault{\textvisiblespace}{%
313   \mbox{\kern.06em\vrule \@height.3ex}%
314   \vbox{\hrule \@width.3em}%
315   \hbox{\vrule \@height.3ex}}

```

Using `\fontdimen3` in the next definition is some sort of a kludge (since it is the interword stretch) but it makes the ellipsis come out right in mono-spaced fonts too (since there it is zero).

```

316 \DeclareTextCommandDefault{\textellipsis}{%
317   .\kern\fontdimen3\font
318   .\kern\fontdimen3\font
319   .\kern\fontdimen3\font}

320 %\DeclareTextCommandDefault{\textregistered}{\textcircled{\scshape r}}
321 \DeclareTextCommandDefault{\textregistered}{\textcircled{%
322   \check@mathfonts\fontsize\sf@size\z@\math@fontsfalse\selectfont R}}
323 \DeclareTextCommandDefault{\texttrademark}{\textsuperscript{TM}}
324 \DeclareTextCommandDefault{\SS}{SS}

325 \DeclareTextCommandDefault{\textordfeminine}{\textsuperscript{a}}
326 \DeclareTextCommandDefault{\textordmasculine}{\textsuperscript{o}}

```

#### 1.4.5 Math material

Some commands can be used in both text and math mode:

```

327 \DeclareRobustCommand{\$}{\ifmmode\mathdollar\else\textdollar\fi}

```

We use `\protected` not `\DeclareRobustCommand` so that `\bigl\{` etc. works inside `\protected@edef`.

```

328 \protected\def{\{\ifmmode\lbrace\else\textbraceleft\fi}
329 \protected\def\}\{\ifmmode\rbrace\else\textbraceright\fi}

330 \DeclareRobustCommand{\P}{\ifmmode\mathparagraph\else\textparagraph\fi}
331 \DeclareRobustCommand{\S}{\ifmmode\mathsection\else\textsection\fi}
332 \DeclareRobustCommand{\dag}{\ifmmode{\dagger}\else\textdagger\fi}
333 \DeclareRobustCommand{\ddag}{\ifmmode{\ddagger}\else\textdaggerdbl\fi}

```

For historical reasons `\copyright` needs `{}` around the definition in maths.

```

334 \DeclareRobustCommand{\_}{%
335   \ifmmode\nfss@text{\textunderscore}\else\textunderscore\fi}
336 \DeclareRobustCommand{\copyright}{%
337   \ifmmode{\nfss@text{\textcopyright}}\else\textcopyright\fi}
338 \DeclareRobustCommand{\pounds}{%
339   \ifmmode\mathsterling\else\textsterling\fi}

340 \DeclareRobustCommand{\dots}{%
341   \ifmmode\mathellipsis\else\textellipsis\fi}

342 \let\ldots\dots

```

395 <latexrelease>\EndIncludeInRelease

```

## 1.5 Definitions for the OT1 encoding

The definitions for the ‘T<sub>E</sub>X text’ (OT1) encoding.

Declare the encoding.

```

396 <*OT1>
397 \DeclareFontEncoding{OT1}{-}{}

```

Providing font substitution is essential if accents are missing in a font and substitution tries to find it elsewhere. Without it you might receive a “Corrupted NFSS tables” error.

```

398 \DeclareFontSubstitution{OT1}{cmr}{m}{n}

```

Declare the accents.

```

399 \DeclareTextAccent{"}{OT1}{127}
400 \DeclareTextAccent{'}{OT1}{19}
401 \DeclareTextAccent{.}{OT1}{95}
402 \DeclareTextAccent{=}{OT1}{22}
403 \DeclareTextAccent{^}{OT1}{94}
404 \DeclareTextAccent{'}{OT1}{18}
405 \DeclareTextAccent{~}{OT1}{126}
406 \DeclareTextAccent{H}{OT1}{125}
407 \DeclareTextAccent{u}{OT1}{21}
408 \DeclareTextAccent{v}{OT1}{20}
409 \DeclareTextAccent{r}{OT1}{23}

```

Some accents have to be built by hand: Note that `\ooalign` and `\o@lign` must be inside a group. In these definitions we no longer use the helper function `\sh@ft` from `plain.tex` since that now has two incompatible definitions.

```

410 \DeclareTextCommand{\b}{OT1}[1]
411   {\hmode\bgroup\o@lign{\relax#1\crrcr\hidewidth\ltx@sh@ft{-3ex}%
412     \vbox to.2ex{\hbox{\char22}\vss}\hidewidth}\egroup}
413 \DeclareTextCommand{\c}{OT1}[1]
414   {\leavevmode\setbox\z@\hbox{#1}\ifdim\ht\z@=1ex\accent24 #1%
415     \else\ooalign{\unhbox\z@\crrcr\hidewidth\char24\hidewidth}\fi}
416 \DeclareTextCommand{\d}{OT1}[1]
417   {\hmode\bgroup
418     \o@lign{\relax#1\crrcr\hidewidth\ltx@sh@ft{-1ex}.\hidewidth}\egroup}

```

Declare the text symbols.

```

419 \DeclareTextSymbol{\AE}{OT1}{29}
420 \DeclareTextSymbol{\OE}{OT1}{30}
421 \DeclareTextSymbol{\O}{OT1}{31}
422 \DeclareTextSymbol{\ae}{OT1}{26}
423 \DeclareTextSymbol{\i}{OT1}{16}
424 \DeclareTextSymbol{\j}{OT1}{17}
425 \DeclareTextSymbol{\oe}{OT1}{27}
426 \DeclareTextSymbol{\o}{OT1}{28}
427 \DeclareTextSymbol{\ss}{OT1}{25}
428 \DeclareTextSymbol{\textendash}{OT1}{124}
429 \DeclareTextSymbol{\textendash}{OT1}{123}

```

The `\nobreak\hskip\z@` is there to prevent a break after the hyphen but allow later breaks in the remainder of the word.

```

430 \DeclareTextCommand{\textnonbreakinghyphen}{OT1}{\mbox{-}\nobreak\hskip\z@}
431 \DeclareTextCommand{\textfiguredash}{OT1}{\textendash}
432 \DeclareTextCommand{\texthorizontalbar}{OT1}{\textendash}

```

Using the ligatures helps with OT1 fonts that have `\textexclamdown` and `\textquestiondown` in unusual positions.

```

433 %\DeclareTextSymbol{\textexclamdown}{OT1}{60}

```

```

434 %\DeclareTextSymbol{\textquestiondown}{OT1}{62}
435 \DeclareTextCommand{\textexclamdown}{OT1}{!'}
436 \DeclareTextCommand{\textquestiondown}{OT1}{?' }
437 %\DeclareTextSymbol{\textthyphenchar}{OT1}{'\-}
438 %\DeclareTextSymbol{\textthyphen}{OT1}{'\-}
439 \DeclareTextSymbol{\textquotedblleft}{OT1}{92}
440 \DeclareTextSymbol{\textquotedblright}{OT1}{'\"}
441 \DeclareTextSymbol{\textquoteleft}{OT1}{'\'}
442 \DeclareTextSymbol{\textquoteright}{OT1}{'\'}

```

Some symbols which are faked from others:

```

443 % \DeclareTextCommand{\aa}{OT1}
444 %   {\accent23a}
445 \DeclareTextCommand{\L}{OT1}
446   {\leavevmode\setbox\z@\hbox{L}\hb@xt@\wd\z@{\hss\@xxxii L}}
447 \DeclareTextCommand{\l}{OT1}
448   {\hmode\bgroup\@xxxii l\egroup}
449 % \DeclareTextCommand{\AA}{OT1}
450 %   {\leavevmode\setbox\z@\hbox{h}\dimen@ht\z@\advance\dimen@-1ex%
451 %     \rlap{\raise.67\dimen@\hbox{\char23}}A}

```

In the OT1 encoding Å has a hand-crafted definition, so we have here the first recorded explicit use of `\DeclareTextCompositeCommand`.

```

452 \DeclareTextCompositeCommand{\r}{OT1}{A}
453   {\leavevmode\setbox\z@\hbox{!}\dimen@ht\z@\advance\dimen@-1ex%
454   \rlap{\raise.67\dimen@\hbox{\char23}}A}

```

The dutch language uses the letter ‘ij’. It is available in T1 encoded fonts, but not in the OT1 encoded fonts. Therefore we fake it for the OT1 encoding.

```

455 \DeclareTextCommand{\ij}{OT1}{%
456   \nobreak\hskip\z@skip i\kern-0.02em\nobreak\hskip\z@skip j}
457 \DeclareTextCommand{\IJ}{OT1}{%
458   \nobreak\hskip\z@skip I\kern-0.02em\nobreak\hskip\z@skip J}

```

In the OT1 encoding, £ and \$ share a slot.

```

459 \DeclareTextCommand{\textdollar}{OT1}{\hmode\bgroup
460   \ifdim \fontdimen\@ne\font >\z@
461     \slshape
462   \else
463     \upshape
464   \fi
465   \char'\$\egroup}
466 \DeclareTextCommand{\textsterling}{OT1}{\hmode\bgroup
467   \ifdim \fontdimen\@ne\font >\z@
468     \itshape
469   \else
470     \fontshape{ui}\selectfont
471   \fi
472   \char'\$\egroup}

```

Here we are adding some more composite commands to the OT1 encoding. This makes the use of certain accents with i compatible with their use with the T1 encoding; this enables them to become true L<sup>A</sup>T<sub>E</sub>X internal representations. However, it will make these accents work a little less fast since a check will always be made for the existence of a composite.

```

473 \DeclareTextComposite{\.}{OT1}{i}{'\i}
474 \DeclareTextComposite{\.}{OT1}{i}{'\i}
475 \DeclareTextCompositeCommand{\'}{OT1}{i}{\@tabacckludge'\i}
476 \DeclareTextCompositeCommand{\'}{OT1}{i}{\@tabacckludge'\i}
477 \DeclareTextCompositeCommand{\^}{OT1}{i}{\^i}
478 \DeclareTextCompositeCommand{\^}{OT1}{i}{\^i}
479 \DeclareTextCompositeCommand{\^}{OT1}{i}{\^i}

T1 encoding is given more extensive set of overloads for \c But here we just adjust
\c{g}.

480 \ifx\textcommaabove\undefined\else
481 \DeclareTextCompositeCommand{\c}{OT1}{g}{\textcommaabove{g}}
482 \fi
483 \</OT1>

```

## 1.6 Definitions for the T1 encoding

The definitions for the ‘Extended T<sub>E</sub>X text’ (T1) encoding.

Declare the encoding.

```

484 \<T1>
485 \DeclareFontEncoding{T1}{}{}
486 \DeclareFontSubstitution{T1}{cmr}{m}{n}

```

Declare the accents.

```

487 \DeclareTextAccent{\'}{T1}{0}
488 \DeclareTextAccent{\'}{T1}{1}
489 \DeclareTextAccent{\^}{T1}{2}
490 \DeclareTextAccent{\^}{T1}{3}
491 \DeclareTextAccent{\^}{T1}{4}
492 \DeclareTextAccent{\^}{T1}{5}
493 \DeclareTextAccent{\^}{T1}{6}
494 \DeclareTextAccent{\^}{T1}{7}
495 \DeclareTextAccent{\^}{T1}{8}
496 \DeclareTextAccent{\^}{T1}{9}
497 \DeclareTextAccent{\^}{T1}{10}

```

Some accents have to be built by hand. Note that \ooalign and \o@lign must be inside a group. In these definitions we no longer use the helper function \sh@ft from plain.tex since that now has two incompatible definitions.

```

498 \DeclareTextCommand{\b}{T1}[1]
499   {\hmode\bgroup\o@lign{\relax#1\crrc\hidewidth\ltx@sh@ft{-3ex}%
500     \vbox to.2ex{\hbox{\char9}\vss}\hidewidth}\egroup}
501 \DeclareTextCommand{\c}{T1}[1]
502   {\leavevmode\setbox\z@\hbox{#1}\ifdim\ht\z@=1ex\accent11 #1%
503     \else\ooalign{\unhbox\z@\crrc
504       \hidewidth\char11\hidewidth}}\fi}
505 \DeclareTextCommand{\d}{T1}[1]
506   {\hmode\bgroup
507     \o@lign{\relax#1\crrc\hidewidth\ltx@sh@ft{-1ex}.\hidewidth}\egroup}
508 \DeclareTextCommand{\k}{T1}[1]
509   {\hmode\bgroup\ooalign{\null#1\crrc\hidewidth\char12}\egroup}
510 \DeclareTextCommand{\textogonekcentered}{T1}[1]
511   {\hmode\bgroup\ooalign{%
512     \null#1\crrc\hidewidth\char12\hidewidth}\egroup}

```

Some symbols are constructed.

Slot 24 contains a small circle intended for construction of these two glyphs.

```

513 \DeclareTextCommand{\textperthousand}{T1}
514   {\%\char 24 }           % space or ‘relax as delimiter?
515 \DeclareTextCommand{\textpertenthousand}{T1}
516   {\%\char 24\char 24 } % space or ‘relax as delimiter?

```

For Maltese, \Hwithstroke and \hwithstroke are needed.

```

517 \DeclareTextCommand{\Hwithstroke}{T1}
518   {%
519     \hmode\bgroup
520     \vphantom{H}%
521     \sbox\z@{H}%
522     \oalign{%
523       H\cr
524       \hidewidth
525       \vrule
526         height \dimexpr 0.7\ht\z@+0.1ex\relax
527         depth  -0.7\ht\z@
528         width   0.8\wd\z@
529       \hidewidth\cr
530     }%
531   \egroup
532 }
533 \DeclareTextCommand{\hwithstroke}{T1}
534   {%
535     \hmode\bgroup
536     \vphantom{h}%
537     \sbox\z@{h}%
538     \oalign{%
539       h\cr
540       \kern0.075\wd\z@
541       \vrule
542         height \dimexpr 0.7\ht\z@+0.1ex\relax
543         depth  -0.7\ht\z@
544         width   0.4\wd\z@
545       \hidewidth\cr
546     }%
547   \egroup
548 }

```

Declare the text symbols.

## 1.7 Definitions for the OMS encoding

The definitions for the ‘ $\TeX$  math symbol’ (OMS) encoding. Even though this is meant to be a math font, it includes some of the standard  $\LaTeX$  text symbols.

Declare the encoding.

```
739 <*OMS>
740 \DeclareFontEncoding{OMS}{-}{-}

Declare the symbols. Note that slot 13 has in places been named \Orb: please root
out and destroy this impolity wherever you find it!

741 \DeclareTextSymbol{\textasteriskcentered}{OMS}{3} % "03
742 \DeclareTextSymbol{\textbackslash}{OMS}{110} % "6E
743 \DeclareTextSymbol{\textbar}{OMS}{106} % "6A
744 \DeclareTextSymbol{\textbardbl}{OMS}{107} % "6B
745 \DeclareTextSymbol{\textbraceleft}{OMS}{102} % "66
746 \DeclareTextSymbol{\textbraceright}{OMS}{103} % "67
747 \DeclareTextSymbol{\textbullet}{OMS}{15} % "0F
748 \DeclareTextSymbol{\textdaggerdbl}{OMS}{122} % "7A
749 \DeclareTextSymbol{\textdagger}{OMS}{121} % "79
750 \DeclareTextSymbol{\textparagraph}{OMS}{123} % "7B
751 \DeclareTextSymbol{\textperiodcentered}{OMS}{1} % "01
752 \DeclareTextSymbol{\textsection}{OMS}{120} % "78
753 \DeclareTextSymbol{\textbigcircle}{OMS}{13} % "0D
754 \DeclareTextCommand{\textcircled}{OMS}[1]{\hmode@bgroup
755 \oalign{%
756 \hfil \raise .07ex\hbox {\upshape#1}\hfil \crcr
757 \char 13 % "0D
758 }%
759 \egroup}
760 </OMS>
```

## 1.8 Definitions for the OML encoding

The definitions for the ‘ $\TeX$  math italic’ (OML) encoding. Even though this is meant to be a math font, it includes some of the standard  $\LaTeX$  text symbols.

Declare the encoding.

```
761 <*OML>
762 \DeclareFontEncoding{OML}{-}{-}

Declare the symbols.

763 \DeclareTextSymbol{\textless}{OML}{'\<}
764 \DeclareTextSymbol{\textgreater}{OML}{'\>}
765 \DeclareTextAccent{\t}{OML}{127} % "7F
766 </OML>
```

## 1.9 Definitions for the OT4 encoding

These definitions are for the Polish extension to the ‘ $\TeX$  text’ (OT1) encoding. This encoding was created by B. Jackowski and M. Ryćko for use with the Polish version of Computer Modern and Computer Concrete. In positions 0–127 it is identical to OT1 but it contains some additional characters in the upper half. The  $\LaTeX$  support was developed by Mariusz Olko.

The PL fonts that use it are available as follows:  
 Metafont sources <ftp://ftp.gust.org.pl/TeX/language/polish/pl-mf.zip>;  
 Font files <ftp://ftp.gust.org.pl/TeX/language/polish/pl-tfm.zip>.  
 Declare the encoding.

```

767 <*OT4>
768 \DeclareFontEncoding{OT4}{-}{-}
769 \DeclareFontSubstitution{OT4}{cmr}{m}{n}

```

Declare the accents.

```

770 \DeclareTextAccent{"}{OT4}{127}
771 \DeclareTextAccent{'}{OT4}{19}
772 \DeclareTextAccent{.}{OT4}{95}
773 \DeclareTextAccent{=}{OT4}{22}
774 \DeclareTextAccent{^}{OT4}{94}
775 \DeclareTextAccent{\'}{OT4}{18}
776 \DeclareTextAccent{\~}{OT4}{126}
777 \DeclareTextAccent{\H}{OT4}{125}
778 \DeclareTextAccent{\u}{OT4}{21}
779 \DeclareTextAccent{\v}{OT4}{20}
780 \DeclareTextAccent{\r}{OT4}{23}

```

The ogonek accent is available only under a e A & E. But we have to provide some definition for \k. Some other accents have to be built by hand as in OT1:

```

781 \DeclareTextCommand{\k}{OT4}[1]{%
782   \TextSymbolUnavailable{\k{#1}}#1}

```

In these definitions we no longer use the helper function \sh@ft from plain.tex since that now has two incompatible definitions.

```

783 \DeclareTextCommand{\b}{OT4}[1]
784   {\hmode\bgroup\o@lign{\relax#1\cr\hidewidth\ltx@sh@ft{-3ex}%
785     \vbox to.2ex{\hbox{\char22}\vss}\hidewidth}\egroup}
786 \DeclareTextCommand{\c}{OT4}[1]
787   {\leavevmode\setbox\z@{\hbox{#1}\ifdim\ht\z@=1ex\accent24 #1%
788     \else\o@lign{\unhbox\z@\cr\hidewidth\char24\hidewidth}}\fi}
789 \DeclareTextCommand{\d}{OT4}[1]
790   {\hmode\bgroup
791     \o@lign{\relax#1\cr\hidewidth\ltx@sh@ft{-1ex}.\hidewidth}\egroup}

```

Declare the text symbols.

```

792 \DeclareTextSymbol{\AE}{OT4}{29}
793 \DeclareTextSymbol{\OE}{OT4}{30}
794 \DeclareTextSymbol{\O}{OT4}{31}
795 \DeclareTextSymbol{\L}{OT4}{138}
796 \DeclareTextSymbol{\ae}{OT4}{26}

797 \DeclareTextSymbol{\guillemetleft}{OT4}{174}
798 \DeclareTextSymbol{\guillemetright}{OT4}{175}
799 % old Adobe names
800 \DeclareTextSymbol{\guillemotleft}{OT4}{174}
801 \DeclareTextSymbol{\guillemotright}{OT4}{175}

802 \DeclareTextSymbol{\i}{OT4}{16}
803 \DeclareTextSymbol{\j}{OT4}{17}
804 \DeclareTextSymbol{\l}{OT4}{170}
805 \DeclareTextSymbol{\o}{OT4}{28}
806 \DeclareTextSymbol{\oe}{OT4}{27}

```

```

807 \DeclareTextSymbol{\quotedblbase}{OT4}{255}
808 \DeclareTextSymbol{\ss}{OT4}{25}
809 \DeclareTextSymbol{\textemdash}{OT4}{124}
810 \DeclareTextSymbol{\textendash}{OT4}{123}
811 \DeclareTextSymbol{\textexclamdown}{OT4}{60}
812 %\DeclareTextSymbol{\textthyphenchar}{OT4}{'\-}
813 %\DeclareTextSymbol{\textthyphen}{OT4}{'\-}
814 \DeclareTextSymbol{\textquestiondown}{OT4}{62}
815 \DeclareTextSymbol{\textquotedblleft}{OT4}{92}
816 \DeclareTextSymbol{\textquotedblright}{OT4}{'\'}
817 \DeclareTextSymbol{\textquoteleft}{OT4}{'\'}
818 \DeclareTextSymbol{\textquoteright}{OT4}{'\'}

```

Definition for Å as in OT1:

```

819 \DeclareTextCompositeCommand{\r}{OT4}{A}
820   {\leavevmode\setbox\z@\hbox{!}\dimen@ht\z@\advance\dimen@-1ex%
821     \rlap{\raise.67\dimen@\hbox{\char23}}A}

```

In the OT4 encoding, £ and \$ share a slot.

```

822 \DeclareTextCommand{\textdollar}{OT4}{\hmode@bgroup
823   \ifdim \fontdimen\@ne\font >\z@
824     \slshape
825   \else
826     \upshape
827   \fi
828   \char'\$ \egroup}
829 \DeclareTextCommand{\textsterling}{OT4}{\hmode@bgroup
830   \ifdim \fontdimen\@ne\font >\z@
831     \itshape
832   \else
833     \fontshape{ui}\selectfont
834   \fi
835   \char'\$ \egroup}

```

Declare the composites.

```

836 \DeclareTextComposite{\k}{OT4}{A}{129}
837 \DeclareTextComposite{\'}{OT4}{C}{130}
838 \DeclareTextComposite{\k}{OT4}{E}{134}
839 \DeclareTextComposite{\'}{OT4}{N}{139}
840 \DeclareTextComposite{\'}{OT4}{S}{145}
841 \DeclareTextComposite{\'}{OT4}{Z}{153}
842 \DeclareTextComposite{\.}{OT4}{Z}{155}
843 \DeclareTextComposite{\k}{OT4}{a}{161}
844 \DeclareTextComposite{\'}{OT4}{c}{162}
845 \DeclareTextComposite{\k}{OT4}{e}{166}
846 \DeclareTextComposite{\'}{OT4}{n}{171}
847 \DeclareTextComposite{\'}{OT4}{s}{177}
848 \DeclareTextComposite{\'}{OT4}{z}{185}
849 \DeclareTextComposite{\.}{OT4}{z}{187}
850 \DeclareTextComposite{\'}{OT4}{0}{211}
851 \DeclareTextComposite{\'}{OT4}{o}{243}
852 </OT4>

```

## 1.10 Definitions for the TS1 encoding

```
853 <*TS1>
854 \DeclareFontEncoding{TS1}{-}{-}
855 \DeclareFontSubstitution{TS1}{cmr}{m}{n}
```

Some accents have to be built by hand. Note that `\ooalign` and `\o@lign` must be inside a group.

```
856 \DeclareTextCommand{\capitalcedilla}{TS1}[1]
857   {\hmode@bgroup
858     \ooalign{\null#1\crrc\hidewidth\char11\hidewidth}\egroup}
859 \DeclareTextCommand{\capitalogonek}{TS1}[1]
860   {\hmode@bgroup
861     \ooalign{\null#1\crrc\hidewidth\char12\hidewidth}\egroup}
```

Accents for capital letters.

These commands can be used by the end user either directly or through definitions of the type

```
\DeclareTextCompositeCommand{\'}{T1}{X}{\capitalacute X}
```

None of the latter definitions are provided by default, since they are probably rarely used.

"00 = 0

```
862 \DeclareTextAccent{\capitalgrave}{TS1}{0}
863 \DeclareTextAccent{\capitalacute}{TS1}{1}
864 \DeclareTextAccent{\capitalcircumflex}{TS1}{2}
865 \DeclareTextAccent{\capitaltilde}{TS1}{3}
866 \DeclareTextAccent{\capitaldieresis}{TS1}{4}
867 \DeclareTextAccent{\capitalhungarumlaut}{TS1}{5}
868 \DeclareTextAccent{\capitalring}{TS1}{6}
869 \DeclareTextAccent{\capitalcaron}{TS1}{7}
```

"08 = 8

```
870 \DeclareTextAccent{\capitalbreve}{TS1}{8}
871 \DeclareTextAccent{\capitalmacron}{TS1}{9}
872 \DeclareTextAccent{\capitaldotaccent}{TS1}{10}
```

Tie accents.

The tie accent was borrowed from the `cmmi` font. The `tc` fonts now provide four tie accents, the first two are done in the classical way with asymmetric glyphs hanging out of their boxes; the new ties are centered in their boxes like all other accents. They need a name: please tell us if you know what to call them.

" =

```
873 \DeclareTextAccent{\t}{TS1}{26}
874 \DeclareTextAccent{\capitaltie}{TS1}{27}
875 \DeclareTextAccent{\newtie}{TS1}{28}
876 \DeclareTextAccent{\capitalnewtie}{TS1}{29}
```

Compound word marks.

The text companion fonts contain two compound word marks of different heights, one has `cap_height`, the other `asc_height`.

```
877 \DeclareTextSymbol{\textcapitalcompwordmark}{TS1}{23}
878 \DeclareTextSymbol{\textascendercompwordmark}{TS1}{31}
```

The text companion symbols.

```
879 \DeclareTextSymbol{\textquotestraightbase}{TS1}{13}
```

"10 = 16

```
880 \DeclareTextSymbol{\textquotestraightdblbase}{TS1}{18}
881 \DeclareTextSymbol{\texttwelveudash}{TS1}{21}
882 \DeclareTextSymbol{\textthreequartersemdash}{TS1}{22}
```

"18 = 24

```
883 \DeclareTextSymbol{\textleftarrow}{TS1}{24}
884 \DeclareTextSymbol{\textrightarrow}{TS1}{25}
```

"20 = 32

```
885 \DeclareTextSymbol{\textblank}{TS1}{32}
886 \DeclareTextSymbol{\textdollar}{TS1}{36}
887 \DeclareTextSymbol{\textquotesingle}{TS1}{39}
```

"28 = 40

The symbol `\textasteriskcentered` “\*” is supposed to be always available in TS1 and that is important as it is used in footnote symbols. However, in a few fonts it is missing even though they are otherwise fairly complete. We therefore use a rather elaborate method and check if the slot has a glyph and if not produce a poor man’s version by using a normal “\*” slightly enlarged and somewhat lowered. The main application for this symbol is in footnote symbols and there it should produce a comparable size and show a similar placement.

```
888 %\DeclareTextSymbol{\textasteriskcentered}{TS1}{42} % that’s wanted
889 \DeclareTextCommand \textasteriskcentered{TS1}{%      % and that’s needed
890   \iffontchar\font 42 \char42 \else
891   \begingroup\fontencoding{T1}%
892     \fontsize
893     {\the\dimexpr1.3\dimexpr\fontsize pt\relax}%
894     {\f@baselineskip}%
895     \selectfont
896     \raisebox{-0.7ex}{\dimexpr\height-0.7ex}[0pt]{*}%
897   \endgroup
898   \fi
899 }
```

Note that ’054 is a comma and ’056 is a full stop: these make numbers using oldstyle digits easier to input.

```
900 \DeclareTextSymbol{\textdblhyphen}{TS1}{45}
901 \DeclareTextSymbol{\textfractionsolidus}{TS1}{47}
```

Oldstyle digits.

"30 = 48

```

## 1.11 Definitions for the TU encoding

The TU encoding was originally introduced in the contributed package `fontspec` as a Unicode encoding for XeTeX and LuaTeX.

Normally for these engines, the input consists of Unicode characters encoded in UTF-8. There is therefore little need to use the traditional (ASCII) encoding-specific commands

However, sometimes (e.g. for backwards compatibility) it can be useful to access these Unicode characters via such ASCII-based markup. The commands provided here Cover the characters in the T1 and TS1 encodings, but specified in Unicode position. Almost all the command names have been mechanically extracted from the `inputenc` UTF-8 support, which is essentially doing a reverse mapping from UTF-8 data to L<sup>A</sup>T<sub>E</sub>X LICR commands.

A few additional names for character which were supported in the original `fontspec` version of this file have also been added, even though they are not currently in the default `inputenc` UTF-8 declarations.

```

1004 < *TU>

```

In the base interface the Unicode encoding is always known as TU But we parameterize the encoding name to allow for modelling differences in Unicode support by different fonts.

```

1005 \providecommand\UnicodeEncodingName{TU}

```

As the Unicode encoding, TU, is only currently available with XeTeX or LuaTeX, we detect these engines first, and make adjustments for the differing font loading syntax. For other engines, we issue a warning then abort this file, switching back to T1 encoding.

```

1006 \begingroup\expandafter\expandafter\expandafter\endgroup
1007 \expandafter\ifx\csname XeTeXrevision\endcsname\relax
1008 \begingroup\expandafter\expandafter\expandafter\endgroup
1009 \expandafter\ifx\csname directlua\endcsname\relax

```

Not LuaTeX or XeTeX, abort with a warning.

```

1010 \PackageWarningNoLine{fontenc}
1011   {\UnicodeEncodingName\space
1012    encoding is only available with XeTeX and LuaTeX.\MessageBreak
1013    Defaulting to T1 encoding}
1014 \def\encodingdefault{T1}
1015 \expandafter\expandafter\expandafter\endinput
1016 \else

```

LuaTeX. For LuaTeX 1.10+, define a Lua function to disable any handling by the font code. Otherwise we reload the font without TeX ligatures.

```

1017 \def\UnicodeFontTeXLigatures{+tlig;}
1018 \ifnum\luatexversion<110
1019 \def\reserved@a#1{%
1020 \def\@remove@tlig##1{\@remove@tlig@##1\@nil#1\@nil\relax}
1021 \def\@remove@tlig@##1#1{\@remove@tlig@@##1}}
1022 \edef\reserved@b{\detokenize{+tlig;}}
1023 \expandafter\reserved@a\expandafter{\reserved@b}
1024 \def\@remove@tlig@@#1\@nil#2\relax{#1}
1025 \def\remove@tlig#1{%
1026 \begingroup
1027 \font\remove@tlig
1028 \expandafter\@remove@tlig\expandafter{\fontname\font}%
1029 \remove@tlig
1030 \char#1\relax
1031 \endgroup
1032 }
1033 \else
1034 \newprotectedluacmd\@remove@tlig@@@

```

Now we can define the function. Mostly we just have to insert a protected glyph node, which is a glyph node with subtype 256. But we have to keep track of the current mode to avoid inserting the glyph into a vlist.

```

1035 \now@and@everyjob{\directlua{
1036   local rawchar_func = token.create'\@remove@tlig@@@'.index
1037   local forcehmode = tex.forcehmode
1038   local put_next = token.put_next
1039   local glyph_id = node.id'glyph'
1040   local rawchar_token = token.new(rawchar_func, token.command_id'lua_call')
1041   lua.get_functions_table()[rawchar_func] = function()
1042     local mode = tex.nest.top.mode
1043     if mode == 1 or mode == -1 then
1044       put_next(rawchar_token)
1045       return forcehmode(true)

```

```

1046         end
1047         local n = node.new(glyph_id, 256)
1048         n.font = font.current()
1049         n.char = token.scan_int()
1050         return node.write(n)
1051     end
1052 }

```

Now `\remove@tlig` can be implemented almost as in XeTeX.

```

1053     \def\remove@tlig#1{\@remove@tlig@@@#1\relax}
1054     \fi
1055     \fi
1056 \else
1057     XeTeX
1058     \def\UnicodeFontTeXLigatures{mapping=tex-text;}
1059     \def\remove@tlig#1{\XeTeXglyph\numexpr\XeTeXcharglyph#1\relax}
1060     \fi
1061 \def\UnicodeFontFile#1#2{"[#1]:#2"}
1062 \def\UnicodeFontName#1#2{"#1:#2"}
1063
1064     Declare the encoding
1065 \DeclareFontEncoding\UnicodeEncodingName{}{}
1066
1067     Declare accent command to use a postpended combining character rather than the
1068     TeX \accent primitive
1069 \def\add@unicode@accent#1#2{%
1070     \if\relax\detokenize{#2}\relax~^a0\else#2\fi
1071     \char#1\relax}

```

In its original implementation `\DeclareUnicodeAccent` was given 3 arguments (with second the “Unicode encoding” a.k.a., `\UnicodeEncodingName`) while in other places, e.g., `\DeclareUnicodeComposite`, we always made encoding implicit. So we now change it here to implicit too so that the interfaces become a bit more consistent. To avoid making that a breaking change (even though it only affects two packages on CTAN) we test for #2 being `\UnicodeEncodingName`. This would not catch if somebody used `\DeclareUnicodeAccent{=}{TU-sub}{0304}` but that fortunately hasn’t happened. With the implicit argument you would need to change `\UnicodeEncodingName` instead, as you have to do anyway for the other interface commands.

```

1066 \def\DeclareUnicodeAccent#1#2{%
1067     \edef\reserved@a{#2}%
1068     \edef\reserved@b{\UnicodeEncodingName}%
1069     \ifx\reserved@a\reserved@b
1070         \def\reserved@a{\DeclareUnicodeAccent@{#1}}%
1071     \else
1072         \def\reserved@a{\DeclareUnicodeAccent@{#1}\UnicodeEncodingName}%
1073     \fi
1074     \reserved@a{#2}%
1075 }
1076 \def\DeclareUnicodeAccent@#1#2#3{%
1077     \DeclareTextCommand{#1}{#2}{\add@unicode@accent{#3}}%
1078 }

```

Wrapper around `\DeclareTextCompositeCommand` that uses the declared composite if it exists in the current font or falls back to the default definition for the TU accent if not.

```

1079 {
1080 \catcode\z@=11\relax
1081 \gdef\DeclareUnicodeComposite#1#2#3{%
1082   \def\reserved@a##1##2{%
1083     \DeclareTextCompositeCommand#1\UnicodeEncodingName{#2}{%
1084       \iffontchar\font#3 ##2%
1085       \else ##1\fi}}%
1086   \expandafter\expandafter\expandafter\extract@default@composite
1087   \csname\UnicodeEncodingName\string#1\endcsname{#2}\@nil
1088   \bgroup
1089     \lccode\z@#3 %
1090     \lowercase{\egroup
1091       \expandafter\reserved@a\expandafter{\reserved@b}{^^@}}}%
1092   }

1093 \def\extract@default@composite#1{%
1094   \ifx\@text@composite#1%
1095     \expandafter\extract@default@composite@a
1096   \else
1097     \expandafter\extract@default@composite@b\expandafter#1%
1098   \fi}

1099 \def\extract@default@composite@a#1\@text@composite#2\@nil{%
1100   \def\reserved@b{#2}}
1101 \def\extract@default@composite@b#1#2\@nil{%
1102   \def\reserved@b{#1#2}}

```

Next two commands are simply syntactic sugar to go with the other `\DeclareUnicode...` declarations.

## 2 Package files

This file now also contains some packages that provide access to the more specialised encodings.

### 2.1 The fontenc package

This package allows authors to specify which encodings they will use. For each encoding F00, the package looks to see if the encoding F00 has already been declared. If it has

not, the file `fooenc.def` is loaded. The default encoding is set to be `F00`.

In addition the package at the moment contains extra code to extend the `\@uclclist` (list of upper/lower case pairs) for encodings that involve cyrillic characters. THIS IS A TEMPORARY SOLUTION and will not stay this way forever (or so we hope) but right now we are missing a proper interface for this and didn't wanted to rush it.

1528 `\*package)`

Here we define a macro that extends the `\@uclclist` if needed and afterwards turns itself in a noop.

```

1555 \CYRYO\cyryu\CYRYU\cyrz\CYRZ\cyrzdsc\CYRZDSC\cyrzsh\CYRZH
1556 \cyrzhdsc\CYRZHDSC}%
1557 \let\update@uclc@with@cyrillic\relax
1558 }
```

Here we process each option:

```
1559 \DeclareOption*{%
1560 \let\encodingdefault\CurrentOption
```

From 2020/02/02 release onward we only load the encoding files if they haven't be loaded already. To check this we look at whether `T@encoding` is already defined. If not, we load it later (indicated by setting the switch `@tempswa` to true) and we always load if we are using an older format (or rather in a rollback situation).

```
1561 \@tempswafalse
1562 \@ifl@t@r\fmtversion{2020/02/02}%
1563 {\expandafter\ifx\csname T@\CurrentOption\endcsname\relax
1564 \@tempswatrue\fi}%
1565 {\@tempswatrue}%
```

Load if necessary:

```

1566 \if@tempswa
1567 \edef\reserved@f{%
1568 \lowercase{\def\noexpand\reserved@f{\CurrentOption enc.def}}}%
1569 \reserved@f
1570 \InputIfFileExists\reserved@f
1571 {}{\PackageError{fontenc}%
1572 {Encoding file ‘\reserved@f’ not found.%
1573 \MessageBreak
1574 You might have misspelled the name of the encoding
1575 \MessageBreak
1576 or a required support package (e.g., cyrillic) is
1577 \MessageBreak
1578 missing in your installation}%
1579 {Necessary code for this encoding was not
1580 loaded.\MessageBreak
1581 Thus calling the encoding later on will
1582 produce further error messages.}}%
1583 \let\reserved@f\relax

```

In case the current encoding is one of a list of known cyrillic ones we extend the `\@uclclist`:

```

1584 \expandafter\in@\expandafter{\CurrentOption}%
1585 {T2A,T2B,T2C,X2,LCY,OT2}%
1586 \ifin@

```

But only if it hasn't already been extended. This might happen if there are several calls to fontenc loading one of the above encodings. If we don't do this check the `\@uclclist` gets unnecessarily big, slowing down the processing at runtime.

```

1587 \expandafter\in@\expandafter\cyrillic\expandafter
1588 {\@uclclist}%
1589 \ifin@
1590 \else
1591 \update@uclc@with@cyrillic
1592 \fi
1593 \fi
1594 \fi
1595 }

```

```

1596 \ProcessOptions*

```

We select the new font encoding default (i.e., the last encoding specified in the option list). But this encoding may not work with the current `\fontshape`: e.g., `LY1` is not defined for `cmr` and therefore packages switching to `LY1` usually also change `\rmdefault`. But that only applies at `\begin{document}` so we get a spurious warning if we use what L<sup>A</sup>T<sub>E</sub>X previously used:

```

1597 %\fontencoding\encodingdefault\selectfont

```

So instead we do this here:

```

1598 \usefont\encodingdefault\familydefault\seriesdefault\shapedefault

```

To save some space we get rid of the macro extending the `\@uclclist` (might have happened already).

```

1599 \let\update@uclc@with@cyrillic\relax

```

Finally we pretend that the fontenc package wasn't read in. This allows for using it several times, e.g., in a class file and in the preamble (at the cost of not getting any version info). That kind of hackery shows that using a general purpose package just for loading an encoding is not the right kind of interface for setting up encodings — it will get replaced at some point in the future.

```

1600 \let\@elt\relax
1601 \xdef\@fontenc@load@list{\@fontenc@load@list
1602   \@elt{\csname opt@fontenc.sty\endcsname}}

1603 \global\expandafter\let\csname ver@@fontenc.sty\expandafter\endcsname
1604   \csname ver@fontenc.sty\endcsname
1605 \global\expandafter\let\csname ver@fontenc.sty\endcsname\relax

1609 \endpackage

```

## File 22

# ltcounts.dtx

## 1 Counters and Lengths

Commands for defining and using counters. This file defines the following commands. In each case  $\langle counter \rangle$  may be  $*$  denoting the current counter as set by a previous `\refstepcounter`.

<code>\newcounter</code>	To define a new counter.
<code>\setcounter</code>	To set the value of counters.
<code>\addtocounter</code>	Increase the $\langle counter \rangle$ #1 by the number #2.
<code>\stepcounter</code>	Increase the $\langle counter \rangle$ by one.
<code>\refstepcounter</code>	Increase the $\langle counter \rangle$ by one, also setting the value used by <code>\label</code> .
<code>\value</code>	For accessing the value of the counter as a TeX number (as opposed to <code>\the\langle counter \rangle</code> which expands to the <i>printed</i> representation of $\langle counter \rangle$ )
<code>\arabic</code>	<code>\arabic{\langle counter \rangle}</code> : 1, 2, 3, ...
<code>\roman</code>	<code>\roman{\langle counter \rangle}</code> : i, ii, iii, ...
<code>\Roman</code>	<code>\Roman{\langle counter \rangle}</code> : I, II, III, ...
<code>\alph</code>	<code>\alph{\langle counter \rangle}</code> : a, b, c, ...
<code>\Alph</code>	<code>\Alph{\langle counter \rangle}</code> : A, B, C, ...
<code>\fnsymbol</code>	<code>\fnsymbol{\langle counter \rangle}</code> : *, †, ‡, ...
<code>\counterwithin</code>	<code>\counterwithin[\langle format \rangle]{\langle counter \rangle}{\langle within-counter \rangle}</code> : Resets $\langle counter \rangle$ whenever $\langle within-counter \rangle$ is stepped. Also redefines <code>\the\langle counter \rangle</code> command to produce <code>\the\langle within-counter \rangle.\langle format \rangle{\langle counter \rangle}</code> with <code>\arabic</code> as the default for $\langle format \rangle$ . Star form omits redefining the print representation. The $*$ alias for the current counter may not be used in either argument.
<code>\counterwithout</code>	<code>\counterwithout[\langle format \rangle]{\langle counter \rangle}{\langle within-counter \rangle}</code> : Removes $\langle counter \rangle$ from the reset list of $\langle within-counter \rangle$ . Also redefines <code>\the\langle counter \rangle</code> command to produce <code>\langle format \rangle{\langle counter \rangle}</code> with <code>\arabic</code> as the default for $\langle format \rangle$ . Star form omits redefining the print representation. The $*$ alias for the current counter may not be used in either argument.

1 `\*2ekernel`

### 1.1 Document command and environment counter macros

An environment `foo` has an associated counter defined by the following control sequences:

<code>\c@foo</code>	Contains the counter's numerical value. It is defined by <code>\newcount\foocounter</code> .
<code>\thefoo</code>	Macro that expands to the printed value of <code>\foocounter</code> . For example, if sections are numbered within chapters, and section headings look like Section II-3. The Nature of Counters then <code>\thesection</code> might be defined by: <code>\def\thesection</code> <code>{\@Roman{\c@chapter}-\@arabic{\c@section}}</code>
<code>\p@foo</code>	Macro that expands to a printed 'reference prefix' of counter <code>foo</code> . Any <code>\ref</code> to a value created by counter <code>foo</code> will produce the expansion of <code>\p@foo\thefoo</code> when the <code>\label</code> command is executed. See file <code>ltxref.dtx</code> for an extension of this mechanism.
<code>\cl@foo</code>	List of counters to be reset when <code>foo</code> stepped. Has format <code>\@elt{countera}\@elt{counterb}\@elt{counterc}</code> .

For some environments the counter is named slightly differently, e.g., the counters associated with the `enumerate` environment have the names `enumi`, `enumii`, `enumiii`, and `enumiv` depending on the nesting level.

The same internal macros are defined for counters used by commands such as `\chapter`, `\section`, etc.

**NOTE:**

`\thefoo` and `\p@foo` *must* be defined in such a way that `\edef\bar{\thefoo}` or `\edef\bar{\p@foo}` defines `\bar` so that it will evaluate to the counter value at the time of the `\edef`, even after `\foocounter` and any other counters have been changed. This will happen if you use the standard commands `\@arabic`, `\@Roman`, etc.

The following commands are used to define and modify counters.

`\refstepcounter{<foo>}`

Same as `\stepcounter`, but it also defines `\@currentlabel`, `\@currentHref` and `\@currentcounter` and so that a subsequent `\label{<bar>}` command causes `\ref{<bar>}` to generate the current value of counter `<foo>`.

`\@definecounter{<foo>}`

Initializes counter `<foo>` (with empty reset list), defines `\p@foo` and `\thefoo` to be null and `\theHfoo` to be `\number\value{foo}`. Also adds `<foo>` to `\cl@ckpt` – the reset list of a dummy counter `@ckpt` used for taking checkpoints for the `\include` system.

`\@addtoreset{<foo>}{<bar>}` : Adds counter `<foo>` to the list of counters `\cl@bar` to be reset when counter `<bar>` is stepped.

`\@removefromreset{<foo>}{<bar>}` : Removes counter `<foo>` to the list of counters `\cl@bar` to be reset when counter `<bar>` is stepped.

`\setcounter` `\setcounter{<foo>}{<val>}` : Globally sets `\foocounter` equal to `<val>`.

```

2 \def\setcounter#1#2{%
3   \@ifundefined{c#1}%
4     {\@nocounterr{#1}}%
5     {\global\csname c@#1\endcsname#2\relax}}
```

(End of definition for `\setcounter`.)

`\addtocounter` `\addtocounter{<foo>}{<val>}` Globally increments `\foocounter` by `<val>`.

```

6 \def\addtocounter#1#2{%
7   \@ifundefined{c#1}%
```

```

8      {\@nocounterr{#1}}%
9      {\global\advance\csname c@#1\endcsname #2\relax}}

(End of definition for \addtocounter.)

\newcounter \newcounter{<newctr>}[<oldctr>] Defines <newctr> to be a counter, which is reset when
counter <oldctr> is stepped. If <newctr> already defined produces ‘c@newctr already defined’
error.
10 \def\newcounter#1{%
11   \expandafter\ifdefinable \csname c@#1\endcsname
12   {\@definecounter{#1}}%
13   \@ifnextchar[{\@newctr{#1}}{}}

(End of definition for \newcounter.)

\value \value{<ctr>} produces the value of counter <ctr>, for use with a \setcounter or
\addtocounter command.
14 \def\value#1{\csname c@#1\endcsname}

(End of definition for \value.)

\c@* Make the current counter available as a LATEX counter with name *, so \alph* returns
the current counter as a letter, \stepcounter{*} increments the current counter, etc.
15 \protected\expandafter
16   \def\csname c@*\endcsname{\value\@currentcounter}

(End of definition for \c@*.)

\@newctr
17 \def\@newctr#1[#2]{%
18   \@ifundefined{c@#2}{\@nocounterr{#2}}{\@addtoreset{#1}{#2}}}

(End of definition for \@newctr.)

\stepcounter \stepcounterfoo Globally increments counter \c@F00 and resets all subsidiary counters.
19 \def\stepcounter#1{%
20   \addtocounter{#1}\@ne
21   \begingroup
22     \let\@elt\@stpelt
23     \csname cl@#1\endcsname
24   \endgroup}

(End of definition for \stepcounter.)

\@stpelt Rather than resetting the “within” counter to zero we set it to −1 and then run
\stepcounter that moves it to 0 and also initiates resetting the next level down.

(End of definition for \@Alph.)

\@fnsymbol Typesetting old fashioned footnote symbols. This can be done both in text or math mode
now.

This macro is another example of an ever recurring problem in TEX: Determining
if something is text-mode or math-mode. It is imperative for the decision between text
and math to be delayed until the actual typesetting is done as the code in question may
go through an \edef or \write where an \ifmmode test would be executed prematurely.
Hence in the implementation below, \@fnsymbol is not robust in itself but the parts
doing the actual typesetting are.

```

In the case of `\@fnsymbol` we make use of the robust command `\TextOrMath` which takes two arguments and typesets the first if in text-mode and the second if in math-mode. Note that in order for this command to make the correct decision, it must insert a `\relax` token if run under regular  $\text{\TeX}$ , which ruins any kerning between the preceding characters and whatever awaits typesetting. If you use  $\text{\eTeX}$  as engine for  $\text{\LaTeX}$  (as recommended) this unfortunate side effect is not present.

```

251 </2ekernel>
252 <latexrelease>\IncludeInRelease{2015/01/01}{\@fnsymbol}{Use \TextOrMath}%

273 <latexrelease>\EndIncludeInRelease
274 <*2ekernel>

```

(End of definition for `\@fnsymbol`.)

`\TextOrMath` When using regular  $\text{\TeX}$ , we make this command robust so that it always selects the correct branch in an `\ifmmode` switch with the usual disadvantage of ruining kerning. For the application we use it for here that shouldn't matter. The alternative would be to mimic `\IeC` from `inputenc` but then it will have the disadvantage of choosing the wrong branch if appearing at the beginning of an alignment cell. However, users of  $\text{\eTeX}$  will be pleasantly surprised to get the best of both worlds and no bad side effects.

First some code for checking if we are running  $\text{\eTeX}$  but making sure not to permanently turn `\protected` into `\relax`.

```

275 </2ekernel>
276 <latexrelease>\IncludeInRelease{2015/01/01}{\TextOrMath}{\TextOrMath}%
277 <*2ekernel | latexrelease>
278 \begingroup\expandafter\expandafter\expandafter\endgroup
279 \expandafter\ifx\csname protected\endcsname\relax

```

In case of ordinary  $\text{\TeX}$  we define `\TextOrMath` as a robust command but make sure it always grabs its arguments. If we didn't do this it might very well gobble spaces in the input stream.

```

280 \DeclareRobustCommand\TextOrMath{%
281   \ifmmode \expandafter\@secondoftwo
282   \else \expandafter\@firstoftwo \fi}

```

```

283 \protected@edef\TextOrMath#1#2{\TextOrMath{#1}{#2}}
284 \else

```

For eTeX the situation is similar. The robust macro is a hidden one so that we again avoid problems of gobbling spaces in the input.

```

285 \protected\expandafter\def\csname TextOrMath\space\endcsname{%
286   \ifmmode   \expandafter\@secondoftwo
287   \else      \expandafter\@firstoftwo \fi}
288 \edef\TextOrMath#1#2{%
289   \expandafter\noexpand\csname TextOrMath\space\endcsname

36 </2ekernel>

```

*(End of definition for \@settopoint.)*

## File 24

# ltfssbas.dtx

This file contains the main implementation of the ‘low level’ font selection commands. See other parts of the L<sup>A</sup>T<sub>E</sub>X distribution, or *The L<sup>A</sup>T<sub>E</sub>X Companion* for higher level documentation of the L<sup>A</sup>T<sub>E</sub>X ‘New’ Font Selection Scheme.

**Warning:** The macro documentation is still basically the documentation from the first NFSS release and therefore in some cases probably not completely accurate.

## 1 Preliminary macros

We define a number of macros that will be used later.

```
1 <*2kernel>
2 \message{NFSS base,}
```

`\@nomath` `\@nomath` is used by most macros that will have no effect in math mode. It issues a warning message.

```
3 \def\@nomath#1{\relax\ifmmode
4   \@font@warning{Command \noexpand#1invalid in math mode}\fi}
```

(End of definition for `\@nomath`.)

`\no@alphabet@error` The macro `\no@alphabet@error` is called whenever the user requests a math *alphabet* that is not available in the current *version*. In math mode an error message is produced otherwise the command keeps silent. The argument is the name of the control sequence that identifies the math *alphabet*. The `\relax` at the beginning is necessary to prevent T<sub>E</sub>X from scanning too far in certain situations.

```
5 \gdef\no@alphabet@error#1{\relax \ifmmode
6   \@latex@error{Math\space alphabet\space identifier\space
7     \noexpand#1is\space undefined\space in\space math\space
8     version\space ‘\math@version’}%
9   {Your\space requested\space math\space alphabet\space
10    is\space undefined\space in\space the\space current\space
11    math\space version.^^JCheck\space the\space spelling\space
12    or\space use\space the\space \noexpand\SetMathAlphabet\space
13    command.}
14   \fi}
```

(End of definition for `\no@alphabet@error`.)

`\new@mathgroup` We also give a new name to `\newfam` and `\fam` to avoid verbal confusion (see the introduction).<sup>32</sup>

`\mathgroup`

```
15 %\def\new@mathgroup{\alloc@8\mathgroup\chardef\sixt@@n}
16 \let\mathgroup\fam
17 %\let\newfam\new@mathgroup
18 \@onlypreamble\new@mathgroup
```

(End of definition for `\new@mathgroup` and `\mathgroup`.)

<sup>32</sup>For the same reason it seems advisable to `\let\fam` and `\newfam` equal to `\relax`, but this is commented out to retain compatibility to existing style files.

## 2 Macros for setting up the tables

`\DeclareFontShape` The macro `\DeclareFontShape` takes 6 arguments:

```
19 \def\DeclareFontShape{\begingroup
```

First we restore the catcodes of all characters used in the syntax.

```
20 \nfss@catcodes
```

We use `\expandafter \endgroup` to restore catcode in case something goes wrong with the argument parsing (suggested by Tim Van Zandt)

```
21 \expandafter\endgroup
```

```
22 \DeclareFontShape@}
```

(End of definition for `\DeclareFontShape`.)

`\DeclareFontShape@`

```
23 \</2kernel>
```

```
24 \<*2kernel | latexrelease>
```

```
25 \<latexrelease>\IncludeInRelease{2020/02/02}%
```

```
26 \<latexrelease>{\DeclareFontShape@}{Maybe drop one m}%
```

```
27 \def\DeclareFontShape@#1#2#3#4#5#6{%
```

```
28 \expandafter\ifx\csname #1+#2\endcsname\relax
```

```
29 \<@latex@error{Font family ‘#1+#2’ unknown}\@eha
```

```
30 \else
```

If the series value is incorrectly specified with an extra “m”, e.g., “mc” instead of just “c”, drop the surplus “m” but keep the “m” if it is by its own. In that case also issue a warning that the declaration needs correction.

For this we compare the given value #3 with one where we may have dropped an “m”. If nothing has changes, fine. Otherwise there was a wrong value which is now corrected in `\reserved@b` so we use that and also issue a warning.

```
31 \edef\reserved@a{#3}%
```

```
32 \series@maybe@drop@one@m\reserved@a\reserved@b
```

```
33 \ifx\reserved@a\reserved@b\else
```

```
34 \<@latex@note{Font shape #1/#2/#3/#4 has incorrect series
```

```
35 value ‘#3’.\MessageBreak It should not contain an ‘m’!
```

```
36 Please correct it.\MessageBreak Found}%
```

```
37 \fi
```

```
38 \expandafter
```

```
39 \xdef\csname#1/#2/\reserved@b/#4\endcsname
```

```
40 {\expandafter\noexpand\csname #5\endcsname}%
```

```
41 %
```

Most of the time #6 is empty so using `\let` to `\@empty` saves on space compared to using `\def`. That’s really one of the old space saving techniques and probably not necessary these days.

```
42 \def\reserved@a{#6}%
```

```
43 \global
```

```
44 \expandafter\let\csname#5\endcsname\expandafter\endcsname
```

```
45 \ifx\reserved@a\@empty
```

```
46 \@empty
```

```
47 \else
```

```
48 \reserved@a
```

```
49 \fi
```

```
50 \fi
```

```
51 }
```

```

52 </2ekernel | latexrelease>
53 <latexrelease>\EndIncludeInRelease
54 <latexrelease>\IncludeInRelease{0000/00/00}%
55 <latexrelease>          {\DeclareFontShape@}{Maybe drop one m}%
56 <latexrelease>
57 <latexrelease>\def\DeclareFontShape@#1#2#3#4#5#6{%
58 <latexrelease>  \expandafter\ifx\csname #1+#2\endcsname\relax
59 <latexrelease>    \@latex@error{Font family ‘#1+#2’ unknown}\@eha
60 <latexrelease>  \else
61 <latexrelease>    \expandafter
62 <latexrelease>      \xdef\csname#1/#2/#3/#4\endcsname{\expandafter\noexpand
63 <latexrelease>                                     \csname #5\endcsname}%
64 <latexrelease>    \def\reserved@a{#6}%
65 <latexrelease>    \global
66 <latexrelease>    \expandafter\let\csname#5\endcsname\expandafter\endcsname
67 <latexrelease>    \ifx\reserved@a\@empty
68 <latexrelease>      \@empty
69 <latexrelease>    \else
70 <latexrelease>      \reserved@a
71 <latexrelease>    \fi
72 <latexrelease>  \fi
73 <latexrelease> }
74 <latexrelease>\EndIncludeInRelease
75 <*2ekernel>

```

(End of definition for \DeclareFontShape@.)

\DeclareFixedFont Define a direct font switch that avoids all overhead.

```

76 \def\DeclareFixedFont#1#2#3#4#5#6{%
77   \begingroup
78     \math@fontsfalse
79     \every@math@size{}%
80     \fontsize{#6}\z@
81     \usefont{#2}{#3}{#4}{#5}%
82     \global\expandafter\let\expandafter#1\the\font
83   \endgroup
84 }

```

(End of definition for \DeclareFixedFont.)

\do@subst@correction

```

85 \def\do@subst@correction{%
86   \xdef\subst@correction{%
87     \font@name
88     \global\expandafter\font
89     \csname \curr@fontshape/\f@size\endcsname
90     \noexpand\fontname\font
91     \relax}%

```

Calling \subst@correction after the current group means calling it after we have loaded the substitution font which is done inside a group.

```

92     \aftergroup\subst@correction
93 }

```

(End of definition for \do@subst@correction.)

`\DeclareFontFamily`

```
94 \def\DeclareFontFamily#1#2#3{%  
If we want fast checking for the encoding scheme we can just check for \T@.. being  
defined.
```

```
95 % \@tempswafalse  
96 % \def\reserved@b{#1}%  
97 % \def\cdp@elt##1##2##3##4{\def\reserved@c{##1}%  
98 %       \ifx\reserved@b\reserved@c \@tempswatrue\fi}%  
99 % \cdp@list  
100 % \if@tempswa  
101 % \ifundefined{T@#1}%  
102 %   {%  
103 %     \@latex@error{Encoding scheme ‘#1’ unknown}\@eha  
104 %   }%  
105 %   {%
```

Now we have to define the macro `\<#1>+<#2>` to contain `#3`. But since most of the time `#3` will be empty we use `\let` in a tricky way rather than a simple `\def` since this will save internal memory. We store the argument `#3` in a temporary macro `\reserved@a`.

```
106 \def\reserved@a{#3}%
```

We compare `\reserved@a` with `\@empty`. If these two are the same we `\let` the ‘extra’ macro equal to `\@empty` which is not the same as doing a `\let` to `\reserved@a` — the latter would blow one extra memory location rather than reusing the one from `\@empty`.

```
107 \global  
108 \expandafter\let\csname #1+#2\expandafter\endcsname  
109 \ifx \reserved@a\@empty  
110 \@empty  
111 \else \reserved@a  
112 \fi  
113 }%  
114 }
```

*(End of definition for \DeclareFontFamily.)*

`\cdp@list` We initialize the code page list to be empty.

```
115 \let\cdp@list\@empty  
116 \@onlypreamble\cdp@list
```

*(End of definition for \cdp@list.)*

`\cdp@elt`

```
117 \let\cdp@elt\relax  
118 \@onlypreamble\cdp@elt
```

*(End of definition for \cdp@elt.)*

`\DeclareFontEncoding`

```
119 \def\DeclareFontEncoding{%
```

First we start with ignoring all blanks and newlines since every surplus space in the second or third argument will come out in a weird place in the document.

```

120 \begingroup
121 \nfss@catcodes
122 \expandafter\endgroup
123 \DeclareFontEncoding@
124 \@onlypreamble\DeclareFontEncoding

125 \def\DeclareFontEncoding#1#2#3{%
126 \expandafter
127 \ifx\csname T@#1\endcsname\relax
128 \def\cdp@elt{\noexpand\cdp@elt}%
129 \xdef\cdp@list{\cdp@list\cdp@elt{#1}%
130 \{\default@family\}\{\default@series\}%
131 \{\default@shape\}}%
```

To support encoding dependent commands (like accents) we initialise the command `\encoding`-cmd to be `\changed@cmd`. (See `ltoutenc.dtx` for details.)

```

132 \expandafter\let\csname#1-cmd\endcsname\@changed@cmd
133 \else
134 \@font@info{Redefining font encoding #1}%
135 \fi

136 \global\@namedef{T@#1}{#2}%
137 \global\@namedef{M@#1}{\default@M#3}%
```

Keep a record of the last encoding being declared:

```

138 \xdef\LastDeclaredEncoding{#1}%
139 }
140 \@onlypreamble\DeclareFontEncoding@
```

*(End of definition for \DeclareFontEncoding.)*

`\LastDeclaredEncoding` The last encoding being declared by `\DeclareFontEncoding`.

```

141 \def\LastDeclaredEncoding{}
```

*(End of definition for \LastDeclaredEncoding.)*

`\DeclareFontSubstitution`

```

142 \def\DeclareFontSubstitution#1#2#3#4{%
143 \expandafter
144 \ifx\csname T@#1\endcsname\relax
145 \@latex@error{Encoding scheme ‘#1’ unknown}\@eha
146 \else
147 \begingroup
```

We loop through the `\cdp@list` and rebuild it anew in `\toks@` thereby replacing the defaults for the encoding in question with the new defaults. It is important to store the encoding to test against expanded in `\reserved@a` since it might just be `\LastDeclaredEncoding` that is passed as `#1`.

```

148 \edef\reserved@a{#1}%
149 \toks@{}%
150 \def\cdp@elt##1##2##3##4{%
151 \def\reserved@b{##1}%
152 \ifx\reserved@a\reserved@b
```

Here we use the new defaults but we use `##1` (i.e., the encoding name already stored previously) since we know that it is expanded.

```

153         \addto@hook\toks@{\cdp@elt{##1}{#2}{#3}{#4}}%
154         \else
If \reserved@a and \reserved@b differ then we simply copy from the old list to the new.
155         \addto@hook\toks@{\cdp@elt{##1}{##2}{##3}{##4}}%
156         \fi}%
157         \cdp@list
158         \xdef\cdp@list{\the\toks@}%
159     \endgroup
160     \global
161     \@namedef{D@#1}{%
162         \def\default@family{#2}%
163         \def\default@series{#3}%

```

184 \let\default@T\@empty
185 \let\default@M\@empty

```

(End of definition for `\default@T` and `\default@M`.)

`\DeclareEncodingSubset`

The declaration takes 3 mandatory arguments: an *encoding* for which a subsetting is wanted (currently always `TS1`, and most likely forever), the *font family* for which we declare the subset and finally the *subset* number, with a value between 0 (all of the encoding is supported) and 9 (many glyphs are missing).

For `TS1` the numbers have been chosen in a way that most fonts can be fairly correctly categorized, but the default settings are always conservative, that is they may claim that fewer glyphs are supported than there actually are.

As these days many font families are set up to end in `-LF` (lining figures), `-OsF` (oldstyle figures), etc. the declaration supports a shortcut: if the *font family* name ends in `-*` then the star gets replaced by these common ending, e.g.,

```
\DeclareEncodingSubset{TS1}{Alegreya-*}{2}
```

is the same as writing

```
\DeclareEncodingSubset{TS1}{Alegreya-LF}{2}
\DeclareEncodingSubset{TS1}{Alegreya-OsF}{2}
\DeclareEncodingSubset{TS1}{Alegreya-TLF}{2}
\DeclareEncodingSubset{TS1}{Alegreya-TOsF}{2}
```

If only some are needed then one can define them individually but in many cases all four are wanted, hence the shortcut.

The coding of the declaration has no error checking as it is mostly for internal use.

```
186 \def\DeclareEncodingSubset#1#2{%
187   \DeclareEncodingSubset@aux{#1}#2*\DeclareEncodingSubset@aux
188 }
189 \def\DeclareEncodingSubset@aux#1#2*#3\DeclareEncodingSubset@aux#4{%
if #3 is empty then there was no star, otherwise we define all four variants.
190   \expandafter\ifx\expandafter X\detokenize{#3}X%
191     \@DeclareEncodingSubset{#1}{#2}{#4}%
192   \else
193     \@DeclareEncodingSubset{#1}{#2LF}{#4}%
194     \@DeclareEncodingSubset{#1}{#2TLF}{#4}%
195     \@DeclareEncodingSubset{#1}{#2OsF}{#4}%
196     \@DeclareEncodingSubset{#1}{#2ToSF}{#4}%
197   \fi
198 }
```

The subset info is stored in a command with the name `\family:subset` so if that already exists we change otherwise declare a subset.

```
199 \def\@DeclareEncodingSubset#1#2#3{%
200   \@ifundefined{#1:#2}%
201     {\font@info{Setting #2 sub-encoding to #1/#3}}%
202     {\font@info{Changing #2 sub-encoding to #1/#3}}%
This declaration should be usable in .fd files and therefore has to make its definition globally, because such files can get loaded in random places.
203   \global\@namedef{#1:#2}{#3}}
```

(End of definition for `\DeclareEncodingSubset`.)

**\CheckEncodingSubset** The command `\CheckEncodingSubset` will check if the current font family has the right encoding subset to typeset a certain command. It takes five arguments as follows: first argument is either `\UseTextSymbol`, `\UseTextAccent` depending on whether or not the symbol is a text symbol or a text accent.

The second argument is the encoding from which this symbol should be fetched.

The third argument is either a fake accessor command or an error message. the code in that argument (if ever executed) receives two arguments: `#2` and `#5` of `\CheckEncodingSubset`.

Argument four is the subset encoding id to test against: if this value is higher than the subset id of the current font family then we typeset the symbol, i.e., execute `#1{#2}#5` otherwise it runs `#3#5`, e.g., to produce an error message or fake the glyph somehow.

Argument five is the symbol or accent command that is being checked.

For usage examples see definitions in `ltxtextcomp.dtx`.

`\DeclarePreloadSizes`

```

248 \def\DeclarePreloadSizes#1#2#3#4#5{%
249   \@ifundefined{T@#1}%
250   {\@latex@error{Encoding scheme ‘#1’ unknown}\@eha}%
251   {%

```

Don’t know at the moment what this group here does!

```

252   \begingroup

```

We define a macro `\reserved@f`<sup>33</sup> that grabs the next *size* and loads the corresponding font. This is done by delimiting `\reserved@f`’s only argument by the token `,` (comma).

```

253   \def\reserved@f##1,{%

```

The end of the list will be detected when there are no more elements, i.e. when `\reserved@f`’s argument is empty. The trick used here is explained in Appendix D of the *T<sub>E</sub>Xbook*: if the argument is empty the `\if` will select the first clause and `\let \reserved@f equal to \relax`. (We use the `>` character here since it cannot appear in font file names.)

```

254       \if>##1>%
255       \let\reserved@f\relax
256       \else

```

Otherwise, we define `\font@name` appropriately and call `\pickup@font` to do the work. Note that the requested `\curr@fontshape` combination must have been defined, or you will get an error. The definition of `\font@name` is carried out globally to be consistent with the rest of the code in this file.

```

257       \xdef\font@name{\csname#1/#2/#3/#4/##1\endcsname}%
258       \pickup@font

```

Now we forget the name of the font just loaded. More precisely, we set the corresponding control sequence to `\relax`. This means that later on, when the font is first used, the macro `\define@newfont` is called again to execute the ‘extra’ macro for this font.

```

259       \global\expandafter\let\font@name\relax
260   \fi

```

Finally we call `\reserved@f` again to process the next *size*. If `\reserved@f` was `\let equal to \relax` this will end the macro.

```

261       \reserved@f}%

```

We finish with reinserting the list of sizes after the `\reserved@f` macro and appending an empty element so that the end of the list is recognized properly.

```

## 3 Selecting a new font

### 3.1 Macros for the user

`\fontencoding` As we said in the introduction a font is described by four parameters. We first define `\f@encoding` macros to specify the wanted *family*, *series*, or *shape*. These are simply recorded in internal macros `\f@family`, `\f@series`, and `\f@shape`, resp. We use `\edef`'s so that the arguments can also be macros.

```

314 \DeclareRobustCommand\fontencoding[1]{%
315   \expandafter\ifx\csname T@#1\endcsname\relax
316     \latex@error{Encoding scheme ‘#1’ unknown}\@eha
317   \else
318     \edef\f@encoding{#1}%
319     \ifx\cf@encoding\f@encoding

```

If the new encoding is the same as the old encoding we have nothing to do. However, in case we had a sequence of several encoding changes without a `\selectfont` in-between we can save processing by making sure that `\enc@update` is `\relax`.

```

320       \let\enc@update\relax
321     \else

```

If current and new encoding differ we define the macro `\enc@update` to contain all updates necessary at `\selectfont` time.

```

322       \let\enc@update\@enc@update
323     \fi
324   \fi
325 }

```

(End of definition for `\fontencoding` and `\f@encoding`.)

`\@enc@update`

```

326 \def\@enc@update{%

```

When `\@enc@update` is executed `\f@encoding` holds the encoding name for the new encoding and `\cf@encoding` the name of the last active encoding.

We start by setting the init command for encoding dependent macros to `\@changed@cmd`.

```

327   \expandafter
328   \let
329   \csname\cf@encoding -cmd\endcsname
330   \@changed@cmd

```

Then we turn the one for the new encoding to `\@current@cmd` (see `ltoutenc.dtx` for further explanations).

```

331   \expandafter
332   \let
333   \csname\f@encoding-cmd\endcsname
334   \@current@cmd

```

We execute the default settings `\default@T`, followed by the one for the new encoding.

```
335 \default@T
336 \csname T@f@encoding\endcsname
```

Finally we change the default substitution values, disable `\enc@update` and make `\f@encoding` officially the current encoding.

```
337 \csname D@f@encoding\endcsname
338 \let\enc@update\relax
339 \let\cf@encoding\f@encoding
340 }
```

*(End of definition for `\@enc@update`.)*

`\enc@update` The default action in `\selectfont` is to do nothing.

```
341 \let\enc@update\relax
```

*(End of definition for `\enc@update`.)*

`\fontfamily` They are now all defined later (and differently).

```
\f@family 342 %\DeclareRobustCommand\fontfamily[1]{\edef\f@family{#1}}
\fontseries 343 %\DeclareRobustCommand\fontseries[1]{\edef\f@series{#1}}
\f@series 344 %\DeclareRobustCommand\fontshape[1]{\edef\f@shape{#1}}
\fontshape
\f@shape
```

*(End of definition for `\fontfamily` and others.)*

`\usefont` Some handy abbreviation if you want to get some particular font in the current size. If also the size should change one has to issue a `\fontsize` command first.

`\fontencoding` needs to do some setup work so we call that, but instead of calling `\fontfamily`, `\fontseries` and `\fontshape` it earlier versions of this code did, we now set `\f@family`, etc. directly. If we would call `\fontseries` or `\fontshape` as it was done in the past, they would now interact with the existing series and shape which is not desired if we intend to use an explicit font shape!

```
345 </2ekernel>
346 <*2ekernel | latexrelease>
347 <latexrelease> \IncludeInRelease{2021/06/01}%
348 <latexrelease> \usefont{Force font face}%
349 \DeclareRobustCommand\usefont[4]{\fontencoding{#1}%
350 \edef\f@family{#2}%
351 \set@target@series{#3}%
352 \edef\f@shape{#4}%
```

Any earlier `\fontseries`, etc. should be canceled and we should switch unconditionally to the requested font face so we drop any code that may have been stored in `\delayed@f@adjustment`.

```
353 \let\delayed@f@adjustment\@empty
354 \selectfont
355 \ignorespaces}
356 </2ekernel | latexrelease>
357 <latexrelease> \EndIncludeInRelease
358 <latexrelease> \IncludeInRelease{2020/02/02}%
359 <latexrelease> \usefont{Drop m in usefont}%
360 <latexrelease>
361 <latexrelease> \DeclareRobustCommand\usefont[4]{\fontencoding{#1}%
362 <latexrelease> \edef\f@family{#2}%
```

```

363 <latexrelease> \set@target@series{#3}%
364 <latexrelease> \edef\f@shape{#4}\selectfont
365 <latexrelease> \ignorespaces}
366 <latexrelease>
367 <latexrelease>\EndIncludeInRelease
368 <latexrelease>\IncludeInRelease{0000/00/00}%
369 <latexrelease> \usefont{Drop m in usefont}%
370 <latexrelease>
371 <latexrelease>\DeclareRobustCommand\usefont[4]{\fontencoding{#1}%
372 <latexrelease> \edef\f@family{#2}%
373 <latexrelease> \edef\f@series{#3}%
374 <latexrelease> \edef\f@shape{#4}\selectfont
375 <latexrelease> \ignorespaces}
376 <latexrelease>
377 <latexrelease>\EndIncludeInRelease
378 <*2kernel>

```

*(End of definition for \usefont.)*

**\linespread** The command `\linespread` changes the current `\baselinestretch` by calling `\set@fontsize`. The values for `\f@size` and `\f@baselineskip` will be left unchanged.

```

379 \DeclareRobustCommand\linespread[1]
380 { \set@fontsize{#1}\f@size\f@baselineskip}

```

*(End of definition for \linespread.)*

**\fontsize** We also define a macro that allows to specify a size. In this case, however, we also need the value of `\baselineskip`. As the first argument to `\set@fontsize` we pass the current value of `\baselinestretch`. This will either match the internal value (in which case nothing changes) or it will be an updated value due to a user change of that macro using `\renewcommand`. If we would pass the internal `\f@linespread` such a change would be effectively overwritten by a size change.

```

381 \DeclareRobustCommand\fontsize[2]
382 { \set@fontsize\baselinestretch{#1}{#2}}

```

*(End of definition for \fontsize.)*

**\f@linespread** This macro holds the current internal value for `\baselinestretch`.

```

383 \let\f@family\@empty
384 \let\f@series\@empty
385 \let\f@shape\@empty
386 \let\f@size\@empty
387 \let\f@baselineskip\@empty
388 \let\f@linespread\@empty

```

*(End of definition for \f@linespread.)*

**\cf@encoding**

```

389 \let\f@encoding\@empty
390 \let\cf@encoding\@empty

```

*(End of definition for \cf@encoding.)*

`\@defaultunits` The function `\@defaultunits` when wrapped around a `dimen` or `skip` assignment supplies default units. Usage:

```
\@defaultunits\dimen@=#1pt\relax\@nnil
```

Note: the `\relax` is *important*. Other units can be substituted for the ‘pt’ if desired.

We use `\remove@to@nnil` as an auxiliary macros for `\@defaultunits`. It just has to gobble the supplied default unit ‘pt’ or whatever, if it wasn’t used in the assignment.

```
391 \def\@defaultunits{\afterassignment\remove@to@nnil}
```

(End of definition for `\@defaultunits`.)

`\strip@pt` This macro strips the characters `pt` produced by using `\the` on a `dimen` register.

`\rem@pt`

```
392 \begingroup
393   \catcode‘P=12
394   \catcode‘T=12
395   \lowercase{
396     \def\x{\def\rem@pt##1.##2PT{##1\ifnum##2>\z@.##2\fi}}
397   \expandafter\endgroup\x
398   \def\strip@pt{\expandafter\rem@pt\the}
```

(End of definition for `\strip@pt` and `\rem@pt`.)

`\mathversion` `\mathversion` takes the *math version* name as argument, defines `\math@version` appropriately and switches to the font selected forcing a call to `\glb@settings` if the *version* is known to the system.

```
399 \DeclareRobustCommand\mathversion[1]
400   {\nomath\mathversion
401     \expandafter\ifx\csname mv@#1\endcsname\relax
402     \latex@error{Math version ‘#1’ is not defined}\@eha\else
```

If there has been a frozen math version reset unconditionally to it if we are at `\@math@level` one, so that in the typical case of one bold symbol within the normal version this doesn’t allocate an additional math alphabet. If the nesting is deeper we do nothing, which means alphabet allocations accumulate until the end of the formula. One could do slightly better but that would mean keeping track of the allocations on all levels severately and this is likely to be overkill in nearly all situations.

```
403     \ifcsname mv@#1\endcsname
404     \ifnum \@math@level = \@ne
405       \unconditionally@reset@math@version {#1}%
406     \fi
407   \fi
408   \edef\math@version{#1}%
```

We need to force a math font setup both now and at the point where we return to the previous math version. Forcing a math font setup can simply be done by setting `\glb@currsize` to an invalid value since this will trigger the setup when the formula starts.

```
409   \gdef\glb@currsize{}
```

When the scope of the current `\mathversion` ends we need to restore the old setup. However this time we need to force it directly at least if we are inside math, otherwise we could wait. Another way to enhance this code here is to do the setting only if the version really has changed after all. This might be interesting in case of `amstext` and `boldsymbol`.

```
410         \aftergroup\glb@settings
411         \fi}
```

Resetting the math version unconditionally means that we have to copy the frozen version to `\mv@#1` and also reset the counter `\c@mv@#1` to the number of math alphabets allocated in the frozen version.

```
412 \ExplSyntaxOn
413 \cs_new_protected:Npn \unconditionally@reset@math@version #1 {
414   \cs_gset_eq:cc { mv@#1 }{ mv@#1@frozen }
415   \int_gset:cn { c@mv@#1 }{ \tl_use:c {g__nfss_frozen_mv_ #1 _tl} }
416 }
417 \ExplSyntaxOff
```

*(End of definition for \mathversion and \math@version.)*

If  $\TeX$  would support a hook just before the end of a formula (opposite of `\everymath` so to speak) the implementation of the algorithm would be much simpler because in that case we would set up the correct math fonts at this point without having to worry about incorrect settings due to nesting. The same would be true if in  $\LaTeX$  the use of `$` (as the primitive  $\TeX$  command) would be impossible and instead only a higher-level interface would be available. Note that this does not mean that a `$` couldn't be the short-hand for starting and stopping that higher-level interface, it only means that the direct  $\TeX$  function must be hidden.

Anyway, since we don't have this and won't have it in  $\LaTeX 2_\epsilon$  we need to implement it in a somewhat slower way.

We test for the current math font setup on entry of a formula, i.e., on the hooks `\everymath` and `\everydisplay`. But since these hooks may contain user data we provide ourselves with an internal version of these hooks which stays frozen.

```
\frozen@everymath New internal names for \everymath and \everydisplay.
\frozen@everydisplay
418 \let\frozen@everymath\everymath
419 \let\frozen@everydisplay\everydisplay
```

*(End of definition for \frozen@everymath and \frozen@everydisplay.)*

```
\everymath Now we provide now user hooks that will be called in the frozen internals.
\everydisplay
420 \newtoks\everymath
421 \newtoks\everydisplay
```

*(End of definition for \everymath and \everydisplay.)*

```
\@math@level This counter records the nesting level of math within math.
422 \newcount\@math@level
```

*(End of definition for \@math@level.)*

`\frozen@everydisplay` Now we define the behaviour of the frozen hooks: first check the math setup then call the user hook.

The check code may push tokens after the math formula with `\aftergroup` and they would prevent a `$$` from dropping following spaces. We therefore use a switch to be set as the first thing after the group so that following code can determine if there was a display or some inline math (in the latter case we better not drop spaces). After setting the switch we also have to place `\ignorespaces` because setting the switch may be the only thing that happens after the display. The issue with handling of spaces was found in 2022, but it is really a bug fix for the code added in 2021/11.

```

423 </2ekernel>
424 <latexrelease>\IncludeInRelease{2021/11/15}
425 <latexrelease> {\frozen@everydisplay}{Handle spaces after math}%
426 <*2ekernel| latexrelease>
427 \frozen@everydisplay = {%
428   \aftergroup\@ignoretrue \aftergroup\ignorespaces

```

Record that we entered another math level.

```

429   \advance\@math@level\@ne
430   \check@mathfonts
431   \the\everydisplay}

```

*(End of definition for \frozen@everydisplay.)*

`\frozen@everymath` The frozen code for inline math is similar, except that here we do not want to drop following spaces.

```

432 \frozen@everymath = {%
433   \aftergroup\@ignorefalse

```

## 3.2 Macros for loading fonts

`\pickup@font` The macro `\pickup@font` which is used in `\selectfont` is very simple: if the font name is undefined (i.e. not known yet) it calls `\define@newfont` to load it.

```
450 \def\pickup@font{%
451     \expandafter \ifx \font@name \relax
452     \define@newfont
453     \fi}
```

(End of definition for `\pickup@font`.)

`\split@name` `\pickup@font` assumes that `\font@name` is set but it is sometimes called when `\f@family`, `\f@series`, `\f@shape`, or `\f@size` may have the wrong settings (see, e.g., the definition of `\getanddefine@fonts`). Therefore we need a macro to extract font *family*, *series*, *shape*, and *size* from the font name. To this end we define `\split@name` which takes the font name as a list of characters of `\catcode 12` (without the backslash at the beginning) delimited by the special control sequence `\@nil`. This is not very complicated: we first ensure that `/` has the right `\catcode`

```
454 {\catcode'\/=12
```

and define `\split@name` so that it will define our private `\f@encoding`, `\f@family`, `\f@series`, `\f@shape`, and `\f@size` macros.

```
455 \gdef\split@name#1/#2/#3/#4/#5\@nil{\def\f@encoding{#1}%
456                                     \def\f@family{#2}%
457                                     \def\f@series{#3}%
458                                     \def\f@shape{#4}%
459                                     \def\f@size{#5}}}
```

(End of definition for `\split@name`.)

`\curr@fontshape` Abbreviation which may get removed again for speed.

```
460 \def\curr@fontshape{\f@encoding/\f@family/\f@series/\f@shape}
```

(End of definition for `\curr@fontshape`.)

`\define@newfont` Now we can tackle the problem of defining a new font.

```
461 \def\define@newfont{%
```

We have already mentioned that the token list that `\split@name` will get as argument must not start with a backslash. To reach this goal we will set the `\escapechar` to `-1` so that the `\string` primitive will not generate an escape character. To keep this change local we open a group. We use `\begingroup` for this purpose since `\define@newfont` might be called in math mode, and an empty `\bgroup... \egroup` would add an empty Ord atom to the math list and thus affect the spacing.

Also locally redefine `\typeout` so that ‘No file ...fd’ Warnings become Font Info message just sent to the log file.

```
462 \begingroup
463 \let\typeout\@font@info
464 \escapechar\m@ne
```

Then we extract *encoding scheme*, *family*, *series*, *shape*, and *size* from the font name. Note the four `\expandafter`’s so that `\font@name` is expanded first, then `\string`, and finally `\split@name`.

```
465 \expandafter\expandafter\expandafter
466 \split@name\expandafter\string\font@name\@nil
```

If the `\curr@fontshape` combination is not available, (i.e. undefined) we call the macro `\wrong@fontshape` to take care of this case. Otherwise `\extract@font` will load the external font for us.

```

467 % \expandafter\ifx
468 % \csname\curr@fontshape\endcsname \relax
469 % \try@load@fontshape % try always
470 % \fi
471 % \expandafter\ifx
472 % \csname\curr@fontshape\endcsname \relax
473 % \wrong@fontshape\else

```

To allow substitution we call the `curr@fontshape` macro which usually will expand to `\relax` but may hold code for substitution (see `\subst@fontshape` definition).

```

474 % \csname\curr@fontshape\endcsname
475 % \extract@font\fi

```

We are nearly finished and must only restore the `\escapechar` by closing the group.

```

476 \endgroup}

477 \def\try@load@fontshape{%
478   \expandafter
479   \ifx\csname \f@encoding+\f@family\endcsname\relax
480     \font@info{Trying to load font information for
481               \f@encoding+\f@family}%

```

We predefine this combination to be `\@empty` which means that next time we don't try again unnecessary in case we don't find a `.fd` file. If the file contains a `\DeclareFontFamily` command than this setting will be overwritten.

```

482 \global\expandafter\let
483 \csname \f@encoding+\f@family\endcsname \@empty

```

Set the catcodes used in the syntax, but do it only once (this will be restored at the end of the font loading group).

```

484 \nfss@catcodes
485 \let\nfss@catcodes\relax

```

For increased portability make the external filename monospace, but look for the (old style) mixed case filename if the first attempt fails.

On any monospace system this means that the file is looked for twice which takes up time and string space, but at least for this release Check for both names to give people time to re-install their private fd files with lowercase names.

```

486 \edef\reserved@a{%
487   \lowercase{%
488     \noexpand\InputIfFileExists{\f@encoding\f@family.fd}}}%
489 \reserved@a\relax
490 {\input@\f@encoding\f@family.fd}%
491 \fi}

```

*(End of definition for \define@newfont.)*

**\nfss@catcodes** This macro should contain the standard `\catcode` assignments to all characters which are used in the commands found in an `.fd` file and which might have special `\catcodes` in the middle of a document. If necessary, this list can be extended in a package file using a suitable number of `\expandafter`, i.e.,

```

\expandafter\def\expandafter\nfss@catcodes
\expandafter{\nfss@catcodes <additional settings>}

```

Note, that this macro might get executed several times since it is also called by `\DeclareFontShape`, thus it probably should not be misused as a general purpose hook.

```

492 \def\nfss@catcodes{%

```

We start by making `@` a letter and ignoring all blanks and newlines.

```

493     \makeatletter
494     \catcode'\ 9%
495     \catcode'\^^I9%
496     \catcode'\^^M9%

```

Then we set up `\`, `{`, `}`, `#` and `%` in case an `.fd` file is loaded during a verbatim environment.

```

497     \catcode'\\\z@
498     \catcode'\{\@ne
499     \catcode'\}\tw@
500     \catcode'\#6%
501     \catcode'\^7%
502     \catcode'\%14%

```

The we make sure that the important syntax parts have the right `\catcode`.

```

503     \@makeother\<%
504     \@makeother\>%
505     \@makeother\*%
506     \@makeother\.%
507     \@makeother\-%
508     \@makeother\/%
509     \@makeother\[%
510     \@makeother\]%
511     \@makeother\'%
512     \@makeother\'%
513     \@makeother\"%
514 }

```

*(End of definition for \nfss@catcodes.)*

`\LoadFontDefinitionFile` Load and `.fd` files for some encoding and family (if it exists).

```

533 \*2ekernel

```

(End of definition for \LoadFontDefinitionFile.)

`\DeclareFontFamilySubstitution` The idea for this macro is stolen from the `substitutefont` package by Günter Milde, with some modifications and a new name.

Its purpose is to provide characters in a special encoding that are not available in the current font family to be taken from a different family that is visually compatible (or not if you choose badly). For example, you can match the GFS Didot Greek characters with T<sub>E</sub>X Gyre Pagella (Palatino) by specifying

```
\DeclareFontFamilySubstitution{LGR}{qpl}{udidot}
```

This way if you ask for the LGR encoding in for the `qpl` family you get the characters from the `udidot` family substituted.

We need to ensure that the macro is defined with `\nfss@catcodes` in force (not quite sure why at the moment to be honest).

```

534 \</2ekernel>
535 \*2ekernel | latexrelease>
536 \<latexrelease>\IncludeInRelease{2020/02/02}%
537 \<latexrelease>      {\DeclareFontFamilySubstitution}{Provide family substitution}%
538 \beginngroup
539 \nfss@catcodes
540 \gdef\DeclareFontFamilySubstitution#1#2#3{%

```

We only provide a set of silent substitutions. The package also (re)declared the family, but this is incorrect in my eyes and it is better to handle that differently.

Of course the families may still need loading at this point and so we arrange for this. Otherwise we might run into trouble because the necessary `\DeclareFontFamily` has not been seen.

```

541 \LoadFontDefinitionFile{#1}{#2}%
542 \LoadFontDefinitionFile{#1}{#3}%
543 \DeclareFontShape{#1}{#2}{m}{it}{<->ssub * #3/m/it}{}%
544 \DeclareFontShape{#1}{#2}{m}{n}{<->ssub * #3/m/n}{}%
545 \DeclareFontShape{#1}{#2}{m}{sc}{<->ssub * #3/m/sc}{}%
546 \DeclareFontShape{#1}{#2}{m}{sl}{<->ssub * #3/m/sl}{}%

```

These days a few more shapes might be around, so we declare those too. If they don't exist then after the first substitution normal fallbacks will happen.

```

547 \DeclareFontShape{#1}{#2}{m}{sw}{<->ssub * #3/m/sw}{}%
548 \DeclareFontShape{#1}{#2}{m}{scit}{<->ssub * #3/m/scit}{}%
549 \DeclareFontShape{#1}{#2}{m}{scsl}{<->ssub * #3/m/scsl}{}%

```

Same game with `b` and `bx`, for other weights you are on your own:

```

550 \DeclareFontShape{#1}{#2}{b}{it}{<->ssub * #3/b/it}{}%
551 \DeclareFontShape{#1}{#2}{b}{n}{<->ssub * #3/b/n}{}%
552 \DeclareFontShape{#1}{#2}{b}{scit}{<->ssub * #3/b/scit}{}%
553 \DeclareFontShape{#1}{#2}{b}{scsl}{<->ssub * #3/b/scsl}{}%
554 \DeclareFontShape{#1}{#2}{b}{sc}{<->ssub * #3/b/sc}{}%
555 \DeclareFontShape{#1}{#2}{b}{sl}{<->ssub * #3/b/sl}{}%
556 \DeclareFontShape{#1}{#2}{b}{sw}{<->ssub * #3/b/sw}{}%
557 \DeclareFontShape{#1}{#2}{bx}{it}{<->ssub * #3/bx/it}{}%

```

```

558 \DeclareFontShape{#1}{#2}{bx}{n}{<->ssub * #3/bx/n}{}%
559 \DeclareFontShape{#1}{#2}{bx}{scit}{<->ssub * #3/bx/scit}{}%
560 \DeclareFontShape{#1}{#2}{bx}{scsl}{<->ssub * #3/bx/scsl}{}%
561 \DeclareFontShape{#1}{#2}{bx}{sc}{<->ssub * #3/bx/sc}{}%
562 \DeclareFontShape{#1}{#2}{bx}{sl}{<->ssub * #3/bx/sl}{}%
563 \DeclareFontShape{#1}{#2}{bx}{sw}{<->ssub * #3/bx/sw}{}%
564 }

603 <latexrelease>      \global\let\f@shape\default@shape
604 <latexrelease>      \gdef\f@size{#5}%
605 <latexrelease>      \gdef\f@baselineskip{#5pt}%
606 <latexrelease>}}
607 <latexrelease>\EndIncludeInRelease
608 <*2ekernel>
609 \@onlypreamble\DeclareErrorFont

```

(End of definition for \DeclareErrorFont.)

**\wrong@fontshape** Before we come to the macro `\extract@font` we have to take care of unknown `\curr@fontshape` combinations. The general strategy is to issue a warning and to try a default *shape*, then a default *series*, and finally a default *family*. If this last one also fails T<sub>E</sub>X will go into an infinite loop. But if the defaults are set incorrectly one deserves nothing else!

```

610 </2ekernel>
611 <latexrelease>\IncludeInRelease{2015/01/01}{\wrong@fontshape}%
612 <latexrelease>      {Font substitution in preamble}%
613 <*2ekernel | latexrelease>
614 \def\wrong@fontshape{%
615     \csname D@f@encoding\endcsname % install defaults if in math

```

We remember the wanted `\curr@fontshape` combination which we will need in a moment.

```

616     \edef\reserved@a{\csname\curr@fontshape\endcsname}%
617     \ifx\last@fontshape\reserved@a
618         \errmessage{Corrupted NFSS tables}%
619         \error@fontshape
620     \else

```

Then we warn the user about the mess and set the shape to its default.

```

621     \let\f@shape\default@shape

```

If the combination is not known, try the default *series*.

```

622     \expandafter\ifx\csname\curr@fontshape\endcsname\relax
623         \let\f@series\default@series

```

If this is still undefined, try the default *family*. Otherwise give up. We never try to change the encoding scheme!

```

624     \expandafter
625     \ifx\csname\curr@fontshape\endcsname\relax
626         \let\f@family\default@family

```

If we change the font family and we are in the preamble then the corresponding `.fd` file may not been loaded yet. Therefore we try this now. Otherwise equating the requested font shape with the finally selected fontshape below will fail and can result in “NFSS tables corrupted”. After begin document that will not happen as all `.fd` files involved in substitution are loaded at `\begin{document}`.

```

627         \begingroup
628         \try@load@fontshape
629         \endgroup
630     \fi \fi
631 \fi

```

At this point a valid `\curr@fontshape` combination must have been found. We inform the user about this fact.

The `\expandafter\string` here stops  $\TeX$  adding the space that it usually puts after command names in messages. The similar construction with `\@undefined` just produces ‘undefined’, but saves a few tokens.

`\@wrong@font@char` is locally redefined in `\UseTextSymbol` from its normal (empty) definition, to report the symbol generating the font switch.

```
632 \font@warning{Font shape ‘\expandafter\string\reserved@a’
633 \expandafter\@gobble\string\@undefined\MessageBreak
634 using ‘\curr@fontshape’ instead\@wrong@font@char}%
635 \global\let\last@fontshape\reserved@a
```

We change `\@defaultsubs` to produce a warning at the end of the document. The macro `\@defaultsubs` is initially `\relax` but gets changed here if some default font substitution happens. It is then executed in `\enddocument`.

```
636 \gdef\@defaultsubs{%
637 \font@warning{Some font shapes were not available, defaults
638 substituted.\@gobbletwo}}%
```

If we substitute a `\curr@fontshape` combination by the default one we don’t want the warning to be printed out whenever this (unknown) combination is used. Therefore we globally `\let` the macro corresponding to the wanted combination equal to its substitution. This requires the use of four `\expandafter`’s since `\csname...\endcsname` has to be expanded before `\reserved@a` (i.e. the requested combination), and this must happen before the `\let` is executed.

```
639 \global\expandafter\expandafter\expandafter\let
640 \expandafter\reserved@a
641 \csname\curr@fontshape\endcsname
```

Now we can redefine `\font@name` accordingly. This *must* be done globally since it might occur in the group opened by `\define@newfont`. If we would this definition were local the closing `\endgroup` there would restore the old meaning of `\font@name` and then switch to the wrong font at the end of `\selectfont` although the correct font was loaded.

```
642 \xdef\font@name{%
643 \csname\curr@fontshape/\f@size\endcsname}%
```

The last thing this macro does is to call `\pickup@font` again to load the font if it is not defined yet. At this point this code will loop endlessly if the defaults are not well defined.

```
644 \pickup@font}
645 </2ekernel|latexrelease>
646 <latexrelease>\EndIncludeInRelease
647 <latexrelease>\IncludeInRelease{0000/00/00}{\wrong@fontshape}%

680 <*2ekernel>

```

(End of definition for \wrong@fontshape.)

\@wrong@font@char Normally empty but redefined in \UseTextSymbol so that the Font shape undefined message can refer to the symbol causing the problem.

```
681 \let\@wrong@font@char\@empty
```

(End of definition for \@wrong@font@char.)

\@@defaultsubs See above.

```
\@defaultsubs 682 \let\@defaultsubs\relax
```

(End of definition for \@@defaultsubs and \@defaultsubs.)

\strip@prefix In \extract@font we will need a way to recover the replacement text of a macro. This is done by the primitive \meaning together with the macro \strip@prefix (for the details see appendix D of the T<sub>E</sub>Xbook, p. 382).

```
683 \def\strip@prefix#1>{\}
```

(End of definition for \strip@prefix.)

## 4 Assigning math fonts to *versions*

\install@mathalphabet This is just another name for \gdef but we can redefine it if necessary later on.

```
684 \let\install@mathalphabet\gdef
```

(End of definition for \install@mathalphabet.)

\math@fonts

```
685 \let\math@fonts\@empty
```

(End of definition for \math@fonts.)

`\select@group` `\select@group` has four arguments: the new  $\langle\textit{math alphabet identifier}\rangle$  (a control sequence), the  $\langle\textit{math group number}\rangle$ , the extra macro for math mode and the `\curr@fontshape` definition macro name. We first check if we are in math mode.

```
686 %\def\select@group#1#2#3{\relax\ifmmode
```

We do these things locally using `\begingroup` instead of `\bgroup` to avoid the appearance of an empty Ord atom on the math list.

```
687 % \begingroup
```

We set the math fonts for the *family* in question by calling `\getanddefine@fonts` in the correct environment.

```
688 % \escapechar\m@ne
```

```
689 % \getanddefine@fonts{\csname c@mv@\math@version\endcsname}#3%
```

We globally select the math fonts...

```
690 % \globaldefs\@ne \math@fonts
```

... and close the group to restore `\globaldefs` and `\escapechar`.

```
691 % \endgroup
```

As long as no *size* or *version* change occurs the  $\langle\textit{math alphabet identifier}\rangle$  should simply switch to the installed *math group* instead of calling `\select@group` unnecessarily. So we globally redefine the first argument (the new  $\langle\textit{math alphabet identifier}\rangle$ ) to expand into a `\mathgroup` switch and then select this *alphabet*. Note that this redefinition will be overwritten by the next call to a *version* macro. The original code for the end of `\select@group` was

```
\gdef#1{#3\mathgroup #2}#1\fi}
```

i.e. first redefining the  $\langle\textit{math alphabet identifier}\rangle$  and then calling the new definition to switch to the wanted  $\langle\textit{math group}\rangle$ . Now we define the  $\langle\textit{math alphabet identifier}\rangle$  as a call to the `\use@mathgroup` command.

```
692 % \xdef#1{\noexpand\use@mathgroup\noexpand#2%
```

```
693 % {\number\csname c@mv@\math@version\endcsname}}%
```

But this is not sufficient, as we learned the hard way. The problem here is that the loading of the fonts that comprise the alphabet identifier `#1`, as well as the necessary math font assignments is deferred until it is used. This is OK so far, but if the fonts are switched within the current formula (which may happen if a sub-formula is a box that contains a math version switch) the font assignments for `#1` are not restored unless `#1` is used again. This is disastrous since TeX sees the wrong fonts at the end of the math formula, when it converts the math list into a horizontal list.

This is taken into account as follows: When a math alphabet identifier is used for the first time in a certain version it modifies the corresponding macro `\mv@<version>` so that it calls `\getanddefine@fonts` directly in future as well. We use the macro `\extract@alph@from@version` to do this. It takes the math alphabet identifier `#1` and the math version macro as arguments.

```
694 % \expandafter\extract@alph@from@version
```

```
695 % \csname mv@\math@version\expandafter\endcsname
```

```
696 % \expandafter{\number\csname c@mv@\math@version\endcsname}%
```

```
697 % #1%
```

```
698 % \stepcounter{mv@\math@version}%
```

Finally, it is not possible to simply call the new definition since we have an argument (the third argument of `\use@mathgroup` or more exactly the argument of `\math@egroup` if the `margid` option is in force) which would swallow our closing `\fi`. So we use the `\expandafter` technique to remove the `\fi` before the `\use@mathgroup` is expanded.

```
699 %\expandafter #1\fi}
```

(End of definition for `\select@group`.)

`\extract@alph@from@version`

We proceed to the definition of the macro `\extract@alph@from@version`. As stated above, it takes a math alphabet identifier and a math version macro (e.g. `\mv@normal`) as its arguments.

```
700 \def\extract@alph@from@version#1#2#3{%
```

To extract and replace the definition of math alphabet identifier `#3` in macro `#1` we have to recall how this definition looks like: Somewhere in the replacement text of `#1` there is the sequence

```
\install@mathalphabet<math alphabet identifier> #3{%
  <Definitions for >#3}
```

Hence, the first thing we do is to extract the tokens preceding this definitions, the definition itself, and the tokens following it. To this end we define one auxiliary macro `\reserved@a`.

```
701 \def\reserved@a##1\install@mathalphabet#3##2##3\@nil{%
```

When `\reserved@a` is expanded, it will have the tokens preceding the definition in question in its first argument (`##1`), the following tokens in its third argument (`##3`), and the replacement text for the math alphabet identifier `#3` in its second argument. (`##2`). This is then recorded for later use in a temporary macro `\reserved@b`.

```
702 \def\reserved@b{##2}%
```

Additionally, we define a macro `\reserved@c` to reconstruct the definitions for the math version in question from the tokens that will remain unchanged (`##1` and `##3`) and the yet to build new definitions for the math alphabet identifier `#3`.

```
703 \def\reserved@c####1{\gdef#1{##1####1##3}}%
```

Then we execute our auxiliary macro.

```
704 \expandafter\reserved@a#1\@nil
```

OK, so now we have to build the new definition for `#3`. To do so, we first extract the interesting parts out of the old one. The old definition looks like:

```
\select@group<math alphabet identifier>
  <math group number><math extra part>
<curr@fontshape definition>
```

So we define a new temporary macro `\reserved@a` that extracts these parts.

```
705 \def\reserved@a\select@group#3##1##2\@nil{%
```

This macro can now directly rebuild the math version definition by calling `\reserved@c`:

```
706 \reserved@c{%
707   \getanddefine@fonts{#2}##2%
708   \install@mathalphabet#3{%
709     \relax\ifmmode \else \non@alpherr#3\fi
710   \use@mathgroup##1{#2}}%
```

In addition it defines the alphabet the way it should be used from now on.

```
711 \gdef#3{\relax\ifmmode \else \non@alpherr#3\fi
712 \use@mathgroup##1{#2}}}%
```

Finally, we only have to call this macro `\reserved@a` on the old definitions recorded in `\reserved@b`:

```
713 \expandafter\reserved@a\reserved@b\@nil
714 }
```

*(End of definition for \extract@alph@from@version.)*

`\math@bgroup` Here are the default definitions for `\math@bgroup` and `\math@egroup`. We use `\bgroup` instead of `\begingroup` to avoid ‘leaking out’ of style changes. This has the side effect of always producing mathord atoms.

```
715 \let\math@bgroup\bgroup
716 \def\math@egroup#1{#1\egroup}
```

*(End of definition for \math@bgroup and \math@egroup.)*

`\calculate@math@sizes` Here is the default definition for `\calculate@math@sizes` a more elaborate interface is under testing in `mthscale.sty`.

```
717 \gdef\calculate@math@sizes{%
718 \font@info{Calculating\space math\space sizes\space for\space
719 size\space <\f@size>}%
720 \dimen@ \f@size \p@
721 \tempdimb \defaultscriptratio \dimen@
722 \dimen@ \defaultscriptscriptratio \dimen@
723 \expandafter\xdef\csname S@\f@size\endcsname{%
724 \gdef\noexpand\tf@size{\f@size}%
725 \gdef\noexpand\s@size{\strip@pt\tempdimb}%
726 \gdef\noexpand\ssf@size{\strip@pt\dimen@}%
727 \noexpand\math@fontstrue}}
```

*(End of definition for \calculate@math@sizes.)*

`\defaultscriptratio` The default ratio for math sizes is:  
`\defaultscriptscriptratio` 1 to `\defaultscriptratio` to `\defaultscriptscriptratio`.  
 By default this is 1 to .7 to .5.

```
728 \def\defaultscriptratio{.7}
729 \def\defaultscriptscriptratio{.5}
```

*(End of definition for \defaultscriptratio and \defaultscriptscriptratio.)*

`\noaccents@` If we don’t have a definition for `\noaccents@` we provide a dummy.

```
730 \ifx\noaccents@\@undefined
731 \let\noaccents@\@empty
732 \fi
```

*(End of definition for \noaccents@.)*

`\showhyphens` The `\showhyphens` command must be redefined since the version in `plain.tex` uses `\tenrm`. We have also made some further adjustments for its use in L<sup>A</sup>T<sub>E</sub>X.

```

733 </2ekernel>
734 <latexrelease>\IncludeInRelease{2017/01/01}{\showhyphens}%
735 <latexrelease>                {XeTeX support for \showhyphens}%
736 <*2ekernel|latexrelease>
737 \ifx\XeTeXcharclass\@undefined

744     \normalfont
745     \pretolerance\m@ne\tolerance\m@ne\hbadness\z@\showboxdepth\z@\ #1%
746     \color@endgroup}}
747 \else

```

XeT<sub>E</sub>X version. When using system fonts XeT<sub>E</sub>X reports consecutive runs of characters as a single item in box logging, which means the standard `\showhyphens` does not work. This version typesets the text into a narrow box to force hyphenation and then reconstructs a horizontal list with explicit hyphens to generate the display. Note that the `lmr` OpenType font is forced, this works even if the characters are not in the font as hyphenation is attempted due to the width of the space and hyphen character. It would generate spurious Missing Character warnings in the log, these are however suppressed from the terminal and log output by ensuring that `\tracinglostchars` is locally zero.

```

748 \DeclareRobustCommand\showhyphens[1]{%
749   \setbox0\vbox{%

## File 25

# ltfssaxes.dtx

This file contains the implementation for handling extra axes by splitting the series and the shape values into sub-categories. See other parts of the L<sup>A</sup>T<sub>E</sub>X distribution, or *The L<sup>A</sup>T<sub>E</sub>X Companion* for higher level documentation of the L<sup>A</sup>T<sub>E</sub>X Font Selection Scheme.

```
1 <2ekernel>\message{NFSS axes,}
```

Everything in the this file got introduced 2020/02/02, so we use large rollback chunks, only interrupted if necessary.

```
2 <*2ekernel | latexrelease>
```

```
3 <latexrelease>\IncludeInRelease{2025/06/01}%
```

```
4 <latexrelease> {\DeclareFontSeriesChangeRule}{Series change rules}%
```

## 1 Changing the font series

In the original NFSS implementation the series was a single attribute stored in `\f@series` and so one always had to specify both weight and width together. This meant that it was impossible to typeset a paragraph in a condensed font and inside have a few words in bold weight (but still condensed) without doing this manually by requesting `\fontseries{bc}\selectfont`.

The new implementation now works differently, by looking at both the current value of `\f@series` and the requested new series; these are then used to select a new series value. Thus, if the current series is `c` and we ask for `b` we now get `bc`.

This is done by consulting a simple lookup table. This table is configurable (though most likely that flexibility will seldom if ever be needed). Adding or changing entries in this table is done with `\DeclareFontSeriesChangeRule`.

### 1.1 The series lookup table

`\DeclareFontSeriesChangeRule` The macro `\DeclareFontSeriesChangeRule` defines entries in a simple database (implemented as a set of commands) that define mappings from the current series and a requested new series to a result series (and additionally offers an alternative if the desired one is unavailable):

**#1** current `\f@series`

**#2** requested new series

**#3** result (provided this series exists in the given font family)

**#4** alternative result (if **#3** does not exist)

If an `.fd` file has its own substitution rules then **#3** exist and thus **#4** is not applied.

If there is no matching database entry, or if neither the result nor the alternative result exists in this font family, then the requested new series is used (which then may trigger substitutions later on).

```
5 \def\DeclareFontSeriesChangeRule#1#2#3#4{%
```

```
6 \@namedef{series@#1@#2}{{#3}{#4}}}
```

(End of definition for `\DeclareFontSeriesChangeRule`.)

## 1.2 Mapping rules for series changes

The rules set up use explicit series values not `\..default` indirections; my current feeling is that this is in fact better.

With 9 weight values (from `ul` to `ub`) and 9 width values (from `uc` to `ux`), this table is now rather large (far more than 1000 entries), but, on the other hand, the table doesn't change and accessing rules is fast when using a table implemented in this way.

We could alternatively split the axis and maintain weight and width separately, but that would take more processing time and would not allow for setting up explicit exceptions nicely (not sure that this would ever get used though).

Design considerations for mapping entries:

- We make `m` reset both weight and width (as this is how it always worked). To reset just the width `?m` is provided and to reset just the weight `m?` is provided.
- We support “`m<width>`” and “`<weight>m`”, e.g., `mec` to mean “go to medium weight and extra-condensed width”. At the end of the process we automatically drop any leftover `m` in the series name (unless it is just a single `m`).
- If there is no table entry then the requested series is used unconditionally. This means that we usually do not need entries where the second argument (the requested series) and the third argument (the result series) are identical (unless we want to use the fourth argument to specify an alternative result series). In particular, this means:
  - Any request for `m` needs no entry, i.e., there are no entries which have `m` as the second argument.
  - Any request to set both weight and width (e.g., `sbx` or `ulc`) needs no entry. For that reason, there are no entries which have a weight+width as second argument (except for cases involving `bx`, see below). In particular, this is also true for cases involving `m`, e.g., `bm` (bold medium width) which automatically gets reduced to `b`, or `mc` (medium weight condensed) which becomes `c` as a result.

There is one exception: we do have rules for a request for `bx`; this is because the Computer Modern fonts (or related families like Latin Modern) need `bx` as their bold series default (`\bfdefault`), since they only have a `b` series for a restricted set of font faces. Many other font families have only `b` but no `bx`, so we have explicit rules that fall back from `bx` to `b`.

- For each combination of a non-`m` `<weight>` and a non-`m` `<width>`, there are 19 entries which have “`<weight><width>`” as first argument: 8 of them have the weight values from `ul` to `ub` except `m` as second argument, another 8 have the width values from `uc` to `ux` except `m` as second argument, and (further down in this file) there is one entry which has `bx` as second argument and two further entries which have `m?` and `?m` as second argument. Rules which have `m` or a weight+width (other than `bx`) as second argument aren't needed (see above).
- For each non-`m` `<weight>`, there are at least 11 entries which have “`<weight>`” as first argument: 8 of them have the width values from `uc` to `ux` except `m` as second argument, and (further down in this file) there is one entry which has `bx` as second argument and two further entries which have `m?` and `?m` as second argument. Rules which have a single weight value as second argument aren't needed because the

second and third arguments would then be identical. In some cases, there are extra rules which make use of the fourth argument to specify an alternative result series.

- Similarly, for each non- $m$   $\langle width \rangle$ , there are at least 11 entries which have “ $\langle width \rangle$ ” as first argument: 8 of them have the weight values from  $ul$  to  $ub$  except  $m$  as second argument, and (further down in this file) there is one entry which has  $bx$  as second argument and two further entries which have  $m?$  and  $?m$  as second argument. Rules which have a single width value as second argument aren’t needed because the second and third arguments would then be identical. In some cases, there are extra rules which make use of the fourth argument to specify an alternative result series.
- Only a few entries have “alternative” values.

The idea is that you don’t want the normal substitution to kick in because that would reset the shape first and it may be better to stay with  $b$  when a change to  $c$  is requested and  $bc$  doesn’t exist, than to go to first change the shape to  $n$  and then find that  $bc/n$  doesn’t exist either and thus ending up with  $m/n$ .

We do this, for example, when  $sb$ ,  $eb$ , or  $ub$  is requested but can’t be fulfilled. In that case it is better to try to stay with some sort of bold rather than ending up with  $m$ . There are some other cases where an “alternative” value is specified; these are explained below in the appropriate places.

577 \DeclareFontSeriesChangeRule {ec}{eb} {ebec} {bec}
578 \DeclareFontSeriesChangeRule {ec}{ub} {ubec} {bec}

```

There are a number of font families that implement condensed series, but often only **c** and **bc**. Therefore, if we see a weight or width change request that can't be fulfilled we try to stay with **c** or **bc**.

```

579 \DeclareFontSeriesChangeRule {c}{ul} {ulc} {c}
580 \DeclareFontSeriesChangeRule {c}{el} {elc} {c}
581 \DeclareFontSeriesChangeRule {c}{l} {lc} {c}
582 \DeclareFontSeriesChangeRule {c}{sl} {slc} {c}
583 \DeclareFontSeriesChangeRule {c}{sb} {sbc} {bc}
584 \DeclareFontSeriesChangeRule {c}{b} {bc} {}
585 \DeclareFontSeriesChangeRule {c}{eb} {ebc} {bc}
586 \DeclareFontSeriesChangeRule {c}{ub} {ubc} {bc}
587 \DeclareFontSeriesChangeRule {c}{uc} {uc} {c}
588 \DeclareFontSeriesChangeRule {c}{ec} {ec} {c}
589 \DeclareFontSeriesChangeRule {c}{sc} {sc} {c}

590 \DeclareFontSeriesChangeRule {sc}{ul} {ulsc} {}
591 \DeclareFontSeriesChangeRule {sc}{el} {elsc} {}
592 \DeclareFontSeriesChangeRule {sc}{l} {lsc} {}
593 \DeclareFontSeriesChangeRule {sc}{sl} {slsc} {}
594 \DeclareFontSeriesChangeRule {sc}{sb} {bsc} {bsc}
595 \DeclareFontSeriesChangeRule {sc}{b} {bsc} {}
596 \DeclareFontSeriesChangeRule {sc}{eb} {ebsc} {bsc}
597 \DeclareFontSeriesChangeRule {sc}{ub} {ubsc} {bsc}

598 \DeclareFontSeriesChangeRule {m}{sb} {sb} {b}
599 \DeclareFontSeriesChangeRule {m}{eb} {eb} {b}
600 \DeclareFontSeriesChangeRule {m}{ub} {ub} {b}

```

This special rule normally does nothing since nearly every font implements the **b** bold series. The exception are Computer Modern and Latin Modern and fonts based on them. They usually only have **bx**, but then they normally provide an `.fd` file declaration mapping from **b** to **bx** and thus pretend that **b** exists. But in case any of them does not, we offer an alternative result and switch to **bx** if **b** can't be found.

```

601 \DeclareFontSeriesChangeRule {m}{b} {b} {bx}

```

If we are in **b** and a width change is requested that leads to a missing font face we stay in **b** because then the font family probably doesn't implement width changes at all.

917 \DeclareFontSeriesChangeRule {ebuc}{eb} {ebuc} {}

```

In the following rule, we use **eb** instead of **b** in the fourth argument, since **eb** is a better approximation to **ub** than **b** and **ebuc** is already in the first argument and therefore this font face probably actually exists. A similar consideration also applies to some other rules in the following.

```

918 \DeclareFontSeriesChangeRule {ebuc}{ub} {ubuc} {ebuc}
919 \DeclareFontSeriesChangeRule {ebuc}{uc} {ebuc} {}

```

```

920 \DeclareFontSeriesChangeRule {ebuc}{ec} {ebec} {}

Special rules for `lm` etc. aren't needed because if `lm` is requested, it will be used if there is no rule, and that is then reduced to `l` automatically. Same for `mc` and friends.

The following entries handle a request for `bx` and fall back to `b` if that can't be fulfilled.

```

1187 \DeclareFontSeriesChangeRule {uluc}{bx} {bx} {b}
1188 \DeclareFontSeriesChangeRule {ulec}{bx} {bx} {b}
1189 \DeclareFontSeriesChangeRule {ulc}{bx} {bx} {b}

```

Here are the special rules for  $m?$ . We offer  $m$  as alternative result series for all entries where this is not already the result series, because otherwise, if the result series does not exist,  $m?$  would be tried as the series value, which cannot work. (Of course, this does not help if the  $m$  series does not exist either, but this should only affect very few fonts.)

```

1268 \DeclareFontSeriesChangeRule {uluc}{m?} {uc} {m}

1437 <latexrelease>
```

The huge set of declarations below are those from 2020-02-02 plus all from above that were newly added (but now with empty result and alternative result arguments). To compile this list I sorted both together and then dropped entries appearing twice. This is why the sorting is now different from the one above.

### 1.3 Changing to a new series

```

2779 <*2ekernel | latexrelease>
2780 <latexrelease>\IncludeInRelease{2021/06/01}%
2781 <latexrelease> {\fontseries}{delay fontseries update}%

```

**\fontseries** The `\fontseries` command takes one argument which is the requested new font series. In the original implementation it simply saved the expanded value in `\f@series`. Now we do a bit more processing and look up the final value in the font series data base. This is done by `\merge@font@series`. But the lookup should be done within the target family and call to `\fontseries` might be followed by a `\fontfamily` call. So we delay the processing to `\selectfont` and only record the necessary action in `\delayed@f@adjustment`.

```

2782 \DeclareRobustCommand\fontseries[1]{\@forced@seriesfalse
2783   \expandafter\def\expandafter\delayed@f@adjustment\expandafter
2784     {\delayed@f@adjustment\delayed@merge@font@series{#1}}}

```

*(End of definition for \fontseries.)*

**\delayed@f@adjustment** The macro holding the delayed action(s) for use in `\selectfont`.

```

2785 \let\delayed@f@adjustment\@empty

```

*(End of definition for \delayed@f@adjustment.)*

**\fontseriesforce** To change unconditionally to a new series you can use `\fontseriesforce`. Of course, if the series doesn't exist for the current family substitution still happens, but there is not dependency on the current series.

```

2786 \DeclareRobustCommand\fontseriesforce[1]{\@forced@seriestrue
2787   \expandafter\def\expandafter\delayed@f@adjustment\expandafter
2788     {\delayed@f@adjustment\edef\f@series{#1}}}

```

*(End of definition for \fontseriesforce.)*

**\if@forced@series** If the series gets forced we need to know that fact later on.

```

2789 \newif\if@forced@series

```

*(End of definition for \if@forced@series.)*

```

2790 </2ekernel | latexrelease>
2791 <latexrelease>\EndIncludeInRelease
2792 <latexrelease>\IncludeInRelease{2020/02/02}%
2793 <latexrelease> {\fontseries}{delay fontseries update}%
2794 <latexrelease>
2795 <latexrelease>\DeclareRobustCommand\fontseries[1]{\@forced@seriesfalse
2796 <latexrelease> \merge@font@series{#1}}
2797 <latexrelease>\DeclareRobustCommand\fontseriesforce[1]{\@forced@seriestrue
2798 <latexrelease> \edef\f@series{#1}}
2799 <latexrelease>\let\delayed@f@adjustment\@undefined
2800 <latexrelease>

```

For a roll forward we may have to define `\if@forced@series` but this needs doing in a way that  $\TeX$  doesn't see it when skipping over conditionals.

```

2801 <latexrelease>\expandafter\newif\csname if@forced@series\endcsname
2802 <latexrelease>
2803 <latexrelease>\EndIncludeInRelease
2804 <latexrelease>\IncludeInRelease{0000/00/00}%
2805 <latexrelease>                {\fontseries}{delay fontseries update}%
2806 <latexrelease>
2807 <latexrelease>\DeclareRobustCommand\fontseries[1]{\edef\f@series{#1}}
2808 <latexrelease>\let\fontseriesforce\@undefined
2809 <latexrelease>
2810 <latexrelease>\EndIncludeInRelease
2811 <*2ekernel | latexrelease>
2812 <latexrelease>\IncludeInRelease{2020/02/02}%
2813 <latexrelease>    {\merge@font@series}{Merge series values}%

```

`\merge@font@series` We look up the data base value by expanding the right command twice. If no such value exist then the result will be `\relax` otherwise it will be the two brace groups: the desired result and the alternate result. The first case means that the third argument to `\merge@font@series` will be empty.

```

2814 \def\merge@font@series#1{%
2815   \expandafter\expandafter\expandafter
2816   \merge@font@series@
2817   \csname series@\f@series @#1\endcsname
2818   {#1}%
2819   \@nil
2820 }

```

*(End of definition for \merge@font@series.)*

`\merge@font@series@` This now defines the new `\f@series`:

```

2821 \def\merge@font@series@#1#2#3\@nil{%

```

If the third argument is empty there is no database entry for the combination and the second argument holds the new series so we return that.

Originally the test was simply `\ifx!#3!` but that actually dies if `#3` starts with a conditional and in the definition of `\AmSfont` that is actually the case.

```

2822 %\ifcat\expandafter X\detokenize{#1}X%
2823 \def\reserved@a{#3}%
2824 \ifx\reserved@a\@empty
2825   \set@target@series{#2}%
2826 \else

```

Otherwise we check if the desired result for the series (`#1`) exists for the font family and the current shape. All this happens inside `\selectfont` which has already taken care to load the `.fd`, file if necessary.

```

2827 \edef\reserved@a{\f@encoding /\f@family /#1/\f@shape}%
2828 \ifcsname \reserved@a \endcsname

```

If the desired result is available then we use that. However, we do need some post-processing because we need to drop surplus `ms` due to the way naming convention was designed in the '90s (sigh).

```

2829 \set@target@series{#1}%

```

If not, then we try the alternate result (#2).

```
2830     \else
2831         \ifcsname \f@encoding /\f@family /#2/\f@shape \endcsname
```

If the alternate result exist we use that and also issue a warning (or rather a log entry) that we didn't managed to change to the desired font.

```
2832         \set@target@series{#2}%
2833         \@font@shape@subst@warning
```

If that doesn't exist either, then we use the requested series unmodified (again with a warning).

```
2834     \else
2835         \set@target@series{#3}%
2836         \@font@shape@subst@warning
2837     \fi
2838 \fi
2839 \fi
2840 }
```

It is possible that the previous font and the new one are actually identical (and the font was not found because it still needs loading) in which case a warning would look rather odd. So we make a quick check for that (which is the reason why we defined `\@reserveda` above instead of doing inline testing inside `\ifcsname`).

```
2841 \def\@font@shape@subst@warning{%
2842     \edef\reserved@b{\curr@fontshape}%
2843     \ifx\reserved@a\reserved@b \else
2844         \@font@warning{Font shape '\reserved@a' undefined\MessageBreak
2845             using '\reserved@b' instead}%
2846     \fi
2847 }
```

(End of definition for `\merge@font@series@`.)

`\merge@font@series@without@substitution`  
`\merge@font@series@without@substitution@`  
`\delayed@merge@font@series`

`\merge@font@series@without@substitution` works like `\merge@font@series`, i.e., it looks up the combination in the rule base and if there exists an entry it uses it and if not it uses the new series value. However, it doesn't check if there is actually a font face with the new series value as `\merge@font@series` does. This simplified command is used in `\selectfont` at a point where other font attributes are not yet updated so that checking the font face might result incorrect in substitutions.

```
2848 \def\merge@font@series@without@substitution#1{%
2849     \expandafter\expandafter\expandafter
2850     \merge@font@series@without@substitution@
2851     \csname series@\f@series @#1\endcsname
2852     {#1}%
2853     \@nil
2854 }
2855 \def\merge@font@series@without@substitution@#1#2#3\@nil{%
2856     \def\reserved@a{#3}%
2857     \ifx\reserved@a\@empty
2858         \set@target@series{#2}%
2859     \else
2860         \set@target@series{#1}%
2861     \fi
2862 }
```

(End of definition for `\merge@font@series@without@substitution`,  
`\merge@font@series@without@substitution@`, and `\delayed@merge@font@series`.)

`\delayed@merge@font@series` When we delay the merge action in `\fontseries` we first attempt to use merging without substitution. If that results in a non-existing font face the merge is redone in `\selectfont` using a version with substitution. See `\selectfont` for details.

```
2863 \let\delayed@merge@font@series\merge@font@series@without@substitution
```

(End of definition for `\delayed@merge@font@series`.)

`\maybe@load@fontshape` A small helper that we use a couple of times: try loading a fontshape (in a group because `\try@load@fontshape` normalizes catcodes and we also want to change `\typeout` so that it doesn't report missing .fd files on the terminal).

```
2864 \def\maybe@load@fontshape{%
2865   \begingroup
2866   \let \typeout \@font@info
2867   \try@load@fontshape
2868   \endgroup}
```

(End of definition for `\maybe@load@fontshape`.)

`\set@target@series` Finally the code for normalizing the `\f@series` value.

The combined series value determined by the mapping may still contain an `m` that we have to remove (as the .fd files use `c` not `mc` to denote a medium weight condensed series, etc.). We do this in all branches above because a user might have written

```
\DeclareFontSeriesChangeRule {m}{sc}{msc}{mc}
```

instead of using `sc` and `c` as needed in the .fd file.

```
2869 \def\set@target@series#1{%
```

We need to `\edef` the argument first in case it starts with a conditional. Then we check (and perhaps drop) an “m” from the value and assign the result to `\f@series`.

```
2870   \edef\f@series{#1}%
2871   \series@maybe@drop@one@m\f@series\f@series
2872 }
```

(End of definition for `\set@target@series`.)

`\series@maybe@drop@one@m` If the series value is in NFSS notation then it should not contain any “m” unless it is just an “m” by its own. So we need to drop surplus “m”s. But we better don't do this for full names, such as “semibold” as used by `autoinst`, for example. So we test against the possible explicit values that should drop an “m”. After that we assign the result to `#2` for further use.

```
2873 \def\series@maybe@drop@one@m#1{%
2874   \expandafter\series@maybe@drop@one@m@x\expandafter{#1}}
2875
2876 \def\series@maybe@drop@one@m@x#1#2{%
```

The code below is an inline version of the `\in@` macro without the group, so that it works in `\accent`.

```
2877   \def\in@@##1,#1,{}%
2878   \series@check@toks\expandafter{\in@@
2879     ,ulm,elm,lm,slm,mm,slm,bm,ebm,ubm,muc,mec,mc,msc,msx,mx,mex,mux,{},{},#1,}%
2880   \edef\in@@{\the\series@check@toks}%
2881   \ifx\in@@\@empty
```

The default definition for `\bfdefault` etc is actually `b\@empty` so that we can detect if the user has changed the default. However that means a) the above test will definitely fail (maybe something to change) and b) we better use `\edef` on the next line to get rid of it as otherwise the test against `#2` (e.g., `\bfdef@ult`) will fail in other places.

```
2882 \edef#2{#1}%
2883 \else
2884 \edef#2{\expandafter\series@drop@one@m #1m\series@drop@one@m}%
2885 \fi
2886 }
```

As a precaution we use a private toks register not `\toks@` as that is no longer hidden inside the group.

```
2887 \newtoks\series@check@toks
```

*(End of definition for \series@maybe@drop@one@m.)*

`\series@drop@one@m` Drop up to two ms but keep one if that makes the series value empty. Actually, with the current implementation we know that there is at least one in the series value itself and we added one after it, so all we have to do is now returning `#1#2` and dropping the rest.

```
2888 \def\series@drop@one@m#1m#2m#3\series@drop@one@m{%
2889 % \ifx\relax#1#2\relax m\else#1#2\fi
2890 #1#2%
2891 }
```

*(End of definition for \series@drop@one@m.)*

## 2 Changing the shape

Shapes are also split in two axes (though it could be more if that is desirable), essentially building in an “sc” axis.

```
2909 <*2ekernel | latexrelease>
2910 <latexrelease>\IncludeInRelease{2020/02/02}%
2911 <latexrelease> {\ulcshape}{Font shape change rules}%
```

`\DeclareFontShapeChangeRule` The database for shapes is done in exactly the same way, only that it is much smaller and we usually have no alternative shape (or rather it is empty thus not used).

```
2912 \def\DeclareFontShapeChangeRule #1#2#3#4{%
2913   \@namedef{shape@#1@#2}{#{#3}#{#4}}}
```

*(End of definition for \DeclareFontShapeChangeRule.)*

There is kind of the same problem with returning back from `sc` to normal. It sort of needs its own letter. In `fontspec` this was solved by the first time `\upshape` changes `it` or `sl` back (so only `sc` remains) and second time it changes then `sc` back to normal. Maybe that's not a bad way to handle it, but decided for a slightly different approach: `n` always returns to “normal”, ie resets everything and `up` changes italic or slanted to upright and `ulc` undoes small caps.

So we now offer `\normalshape` (using `\shapedefault`) which is normally the same as calling both `\ulcshape` and `\upshape`, only more efficient.

`\ulcshape` To request going back to upper/lowercase we need a new command. It uses `ulc` as shape name but this shape is virtual, i.e., it doesn't exist as a real shape, it is only used as part of the database table entries and thus only appears in the second argument there (but not in the first).

```
2914 \DeclareRobustCommand\ulcshape
2915   {\not@math@alphabet\ulcshape\relax
2916    \fontshape\ulcdefault\selectfont}
2917 \let\ulcdefault\@undefined      % for rollback
2918 \newcommand\ulcdefault{ulc}
```

*(End of definition for \ulcshape, \textulc, and \ulcdefault.)*

`\swshape` New command to select a swash shape. The standard rules put this in the same category as italics or slanted, i.e., if you ask for it then italics are undone. One could provide more complicated rules so that `it + sw` becomes `swit` but given that there are only very few fonts that have swash letters that level of flexibility (these days) would be just resulting in a lot of combinations that do not exist.

```
2919 \DeclareRobustCommand\swshape
2920   {\not@math@alphabet\swshape\relax
2921    \fontshape\swdefault\selectfont}
2922 \let\swdefault\@undefined      % for rollback
2923 \newcommand\swdefault{sw}
```

*(End of definition for \swshape, \textsw, and \swdefault.)*

`\sscshape` New commands to select spaced small capitals. There isn't a single free font that supports it. However, some commercial ones do, so we offer it. It is also possible to produce spaced small capitals from normal small capitals in OTF fonts using `otftotfm` with calls such as

```
otftotfm -e TEXMF/fonts/enc/dvips/base/txnnansx.enc \
SourceSerifPro-Regular.otf -fkern -fliga --feature=smcp \
--letterspacing=80 SourceSerifPro-Regular-ssc-LY1
```

Michael Ummels kindly prepared the necessary rules for `ssc` ages ago, but until recently they managed to hide deep down in my inbox. I finally got around to integrating them (with a few changes) and I also took the opportunity to rationalize (a bit) the rules for the only other uncommon shape, `sw`.

```

2924 \DeclareRobustCommand\sscshape
2925       {\not@math@alphabet\sscshape\relax
2926        \fontshape\sscdefault\selectfont}
2927 \let\sscdefault\@undefined      % for rollback
2928 \newcommand\sscdefault{ssc}

(End of definition for \sscshape, \textssc, and \sscdefault.)

## 2.1 Mapping rules for shape combinations

Many of the entries are commented out as we will get that result without any entry.

```

2944 </2ekernel>
2945 <*2ekernel | latexrelease>
2946 <latexrelease>\IncludeInRelease{2025/06/01}%
2947 <latexrelease>    {\DeclareFontShapeChangeRule}{Rules for ssc and sw}%
2948 %
2949 % \DeclareFontShapeChangeRule {n}{n}    {n}    {}
2950 \DeclareFontShapeChangeRule {n}{it}    {it}    {sl}
2951 \DeclareFontShapeChangeRule {n}{sl}    {sl}    {it}

```

If **sw** is requested but not available (not many font families offer it) we try to fallback to **it** instead of **sw**. That isn't always perfect, because some swash shapes are actually upright, but it is only a fallback and most of the time it would be better than **n**.

```

2952 \DeclareFontShapeChangeRule {n}{sw}    {sw}    {it}
2953 % \DeclareFontShapeChangeRule {n}{sc}    {sc}    {}
2954 \DeclareFontShapeChangeRule {n}{ulc}    {n}    {}
2955 \DeclareFontShapeChangeRule {n}{up}    {n}    {}

```

For the **ssc** shape we make the following general assumptions: if **ssc** $\langle X \rangle$  exists then **sc** $\langle X \rangle$  and  $\langle X \rangle$  also exist in the font. If the **ssc** $\langle X \rangle$  shape doesn't exist but the user had asked for **ssc** we try to replace it by **sc** because we then assume that the current font family simply doesn't have any **ssc** shapes. However, if we are already in some **ssc** shape and a shape change is requested we know that at least some **ssc** shapes exist for the current font family, so rather than falling back to some **sc** shape we try to stay within **ssc** shapes in a fallback situation.

```

2956 \DeclareFontShapeChangeRule {n}{ssc}    {ssc}    {sc}

```

```

2957 % \DeclareFontShapeChangeRule {it}{n} {n} {}
2958 % \DeclareFontShapeChangeRule {it}{it} {it} {}
2959 \DeclareFontShapeChangeRule {it}{sl} {sl} {it}
2960 \DeclareFontShapeChangeRule {it}{sw} {sw} {it}

If neither scit nor scsl exist then sc will be used as a fallback albeit with a log entry,
so except for the latter there will be no change for CM or Latin Modern fonts.

2961 \DeclareFontShapeChangeRule {it}{sc} {scit} {scsl}
2962 \DeclareFontShapeChangeRule {it}{ulc} {it} {}
2963 \DeclareFontShapeChangeRule {it}{up} {n} {}
2964 \DeclareFontShapeChangeRule {it}{ssc} {sscit} {scit}

2965 % \DeclareFontShapeChangeRule {sl}{n} {n} {}
2966 \DeclareFontShapeChangeRule {sl}{it} {it} {sl}
2967 % \DeclareFontShapeChangeRule {sl}{sl} {sl} {}
2968 \DeclareFontShapeChangeRule {sl}{sw} {sw} {it}
2969 \DeclareFontShapeChangeRule {sl}{sc} {scsl} {scit}
2970 \DeclareFontShapeChangeRule {sl}{ulc} {sl} {}
2971 \DeclareFontShapeChangeRule {sl}{up} {n} {}
2972 \DeclareFontShapeChangeRule {sl}{ssc} {sscsl} {scsl}

2973 % \DeclareFontShapeChangeRule {sc}{n} {n} {}
2974 \DeclareFontShapeChangeRule {sc}{it} {scit} {scsl}
2975 \DeclareFontShapeChangeRule {sc}{sl} {scsl} {scit}
2976 \DeclareFontShapeChangeRule {sc}{sw} {scsw} {scit}
2977 % \DeclareFontShapeChangeRule {sc}{sc} {sc} {}
2978 \DeclareFontShapeChangeRule {sc}{ulc} {n} {}

```

The next rule might be a bit surprising, and rightly so. It would be more correct if `sc` were not affected by `up`, so that it remains `sc` as shown in the commented out rule. However, for nearly three decades commands such as `\upshape` or `\textup` changed small caps back to the “normal” shape. So for backward compatibility we keep that behavior.

As a result you are currently typesetting in `scit` or `scsl` using `\upshape` twice will return you to the normal shape too, the first will change to `sc` and the second (because of the rule below) change that to `n`. This is the way `fontspec` implemented its version on this interface, so this rule means we are also compatible with the way `fontspec` behaved. Still it remains an oddity which I would rather liked to have avoided.

```

2979 % \DeclareFontShapeChangeRule {sc}{up} {sc} {}
2980 \DeclareFontShapeChangeRule {sc}{up} {n} {}
2981 % \DeclareFontShapeChangeRule {sc}{ssc} {ssc} {}

2982 % \DeclareFontShapeChangeRule {scit}{n} {n} {}
2983 \DeclareFontShapeChangeRule {scit}{it} {scit} {}
2984 \DeclareFontShapeChangeRule {scit}{sl} {scsl} {scit}
2985 \DeclareFontShapeChangeRule {scit}{sw} {scsw} {scit}
2986 \DeclareFontShapeChangeRule {scit}{sc} {scit} {}
2987 \DeclareFontShapeChangeRule {scit}{ulc} {it} {}

```

The next rule assumes that if `scit` exists then `it` exists as well. If not, the mechanism will save `ulc` in `\f@series`, which most certainly doesn’t exist. So when a font is later selected that would result in a substitution (so no harm done really). Alternatively, we could in this case use `n` as alternative, which may be a bit faster, but such a setup would be so weird in the first place that this isn’t worth the effort.

```

2988 \DeclareFontShapeChangeRule {scit}{up} {sc} {}
2989 \DeclareFontShapeChangeRule {scit}{ssc} {sscit} {scit}

```

```

2990 % \DeclareFontShapeChangeRule {scsl}{n} {n} {}
2991 \DeclareFontShapeChangeRule {scsl}{it} {scit} {scsl}
2992 \DeclareFontShapeChangeRule {scsl}{sl} {scsl} {}

3127 <latexrelease>\DeclareFontShapeChangeRule {sscsw}{up} {ssc} {}
3128 <latexrelease>\EndIncludeInRelease

```

Before 2020-02-02 we don't really care about any existing shape change rules since the mechanism isn't used.

```

3129 <latexrelease>\IncludeInRelease{0000/00/00}%
3130 <latexrelease>      {\DeclareFontShapeChangeRule}{Rules for ssc and sw}%
3131 <latexrelease>\EndIncludeInRelease

```

## 2.2 Changing to a new shape

```

3132 <*2ekernel | latexrelease>
3133 <latexrelease>\IncludeInRelease{2021/06/01}%
3134 <latexrelease>      {\fontshape}{Font shape change}%

```

`\fontshape` Again the `\fontshape` now has to do a lookup to get to its new value in `\f@shape`. The method is exactly the same as in `\fontseries`.

```
3135 \DeclareRobustCommand\fontshape[1]
3136     {\expandafter\def\expandafter\delayed@f@adjustment\expandafter
3137      {\delayed@f@adjustment\delayed@merge@font@shape{#1}}}
```

*(End of definition for \fontshape.)*

`\fontshapeforce` The unconditional version:

```
3138 \DeclareRobustCommand\fontshapeforce[1]
3139     {\expandafter\def\expandafter\delayed@f@adjustment\expandafter
3140      {\delayed@f@adjustment\edef\f@shape{#1}}}
```

*(End of definition for \fontshapeforce.)*

Supporting rollback ...

```
3141 </2ekernel | latexrelease>
3142 <latexrelease>\EndIncludeInRelease
3143 <latexrelease>\IncludeInRelease{2020/02/02}%
3144 <latexrelease>    {\fontshape}{Font shape change}%
3145 <latexrelease>
3146 <latexrelease>\DeclareRobustCommand\fontshape[1]{\merge@font@shape{#1}}
3147 <latexrelease>\DeclareRobustCommand\fontshapeforce[1]{\edef\f@shape{#1}}
3148 <latexrelease>
3149 <latexrelease>\EndIncludeInRelease

3150 <latexrelease>\IncludeInRelease{0000/00/00}%
3151 <latexrelease>    {\fontshape}{Font shape change}%
3152 <latexrelease>
3153 <latexrelease>\DeclareRobustCommand\fontshape [1]{\edef\f@shape{#1}}
3154 <latexrelease>\let\fontshapeforce\@undefined
3155 <latexrelease>
3156 <latexrelease>\EndIncludeInRelease

3157 <*2ekernel | latexrelease>
3158 <latexrelease>\IncludeInRelease{2020/02/02}%
3159 <latexrelease>    {\merge@font@shape}{Font shape change rules}%
```

`\merge@font@shape` Look up the database entry (if existing) and act accordingly.

```
3160 \def\merge@font@shape#1{%
3161     \expandafter\expandafter\expandafter
3162     \merge@font@shape@
3163     \csname shape@f@shape @#1\endcsname
3164     {#1}%
3165     \@nil
3166 }
```

*(End of definition for \merge@font@shape.)*

`\merge@font@shape@` Same game now, except that we look at shapes not series values and we can set the shape without the complication of dropping “m”s from the name as we had to for the series.

```
3167 \def\merge@font@shape@#1#2#3\@nil{%
3168     \def\reserved@a{#3}%
3169     \ifx\reserved@a\@empty
3170         \edef\f@shape{#2}%
3171     \else
```

`\reserved@a` is used in `\@font@shape@subst@warning` so we have to define it in addition to do the `\ifcstype` test

```

3172 \edef\reserved@a{\f@encoding /\f@family /\f@series/#1}%
3173 \ifcstype \reserved@a\endcstype
3174 \edef\f@shape{#1}%
3175 \else
3176 \ifcstype \f@encoding /\f@family /\f@series/#2\endcstype
3177 \edef\f@shape{#2}%
3178 \@font@shape@subst@warning
3179 \else
3180 \edef\f@shape{#3}%
3181 \@font@shape@subst@warning
3182 \fi
3183 \fi
3184 \fi
3185 }

```

*(End of definition for \merge@font@shape@.)*

`\merge@font@shape@without@substitution`  
`\merge@font@shape@without@substitution@`  
`\delayed@merge@font@shape`

See definition of `\selectfont` for how these macros are used.

```

3186 \def\merge@font@shape@without@substitution#1{%
3187 \expandafter\expandafter\expandafter
3188 \merge@font@shape@without@substitution@
3189 \cstype shape@\f@shape @#1\endcstype
3190 {#1}%
3191 \@nil
3192 }
3193 \def\merge@font@shape@without@substitution@#1#2#3\@nil{%
3194 \def\reserved@a{#3}%
3195 \ifx\reserved@a\@empty
3196 \edef\f@shape{#2}%
3197 \else
3198 \edef\f@shape{#1}%
3199 \fi
3200 }
3201 \let\delayed@merge@font@shape\merge@font@shape@without@substitution

```

*(End of definition for \merge@font@shape@without@substitution,  
\merge@font@shape@without@substitution@, and \delayed@merge@font@shape.)*

`\normalshape` `\normalshape` resets both sub-axes if the default rules are used.

```

3202 \protected\def\normalshape
3203 {\not@math@alphabet\normalshape\relax
3204 \fontshape\shapedefault\selectfont}%

```

*(End of definition for \normalshape.)*

### 3 Make sure we win ...

This code implements one aspect of what the package `fontaxes` provide. So its redefinitions for the various shape commands, such as `\itshape` should no longer happen. We therefore force the standard definitions at `\AtBeginDocument` (later when this is defined). Once `fontaxes` is no longer doing such redefinitions that could be taken out again.

We use a separate macro so that we can easily disable this (in case of rollback).

`\reinstall@nfss@defs` I use `\protected` here not `\DeclareRobustCommand` to avoid extra status lines.

```

3205 \def\reinstall@nfss@defs{%
3206   \protected\def\upshape
3207     {\not@math@alphabet\upshape\relax
3208      \fontshape\updefault\selectfont}%

## File 26

# ltfsstrc.dtx

## 1 Introduction

This package contains the code for tracing font loading and font changes. It basically overlays some of the low-level functions of NFSS with additional code used for tracing.

The package accepts the following options:

**errorshow** Write all information about font changes etc. only to the transcript file unless an error happens. This means that information about font substitution will not be shown on the terminal.

**warningshow** Show all NFSS warnings on the terminal. This setting corresponds to the default behaviour of NFSS if the `tracefnt` package is *not* loaded!

**infoshow** Show all NFSS warning and all NFSS info messages (that are normally only written to the transcript file) also on the terminal. This is the default if the `tracefnt` package is loaded.

**debugshow** In addition to **infoshow** show also changing of math fonts as far as possible (this option can produce a large amount of output).

**loading** Show the name of external fonts when they are loaded. This option shows only “newly” loaded fonts not those already preloaded in the format or the class file before the `tracefnt` package became active.

**pausing** Turn all font warnings into errors so that L<sup>A</sup>T<sub>E</sub>X will stop.

## 2 A driver for this document

The next bit of code contains the documentation driver file for T<sub>E</sub>X, i.e., the file that will produce the documentation you are currently reading. It will be extracted from this file by the DOCSTRIP program.

When this file is processed directly by L<sup>A</sup>T<sub>E</sub>X this will produce the documentation as well.

```
1 <*driver>
2 \documentclass{ltxdoc}
3
4
5 %\OnlyDescription % comment out for implementation details
6
7 \begin{document}
8   \DocInput{ltfsstrc.dtx}
9 \end{document}
10 </driver>
```

### 3 The Implementation

**Warning:** Read the macro documentation with a grain of salt. It is still basically the documentation from the first NFSS release and therefore in some cases probably not completely accurate.

If we are making a package file it is a good idea to test whether we are running under 2e. This code is actually placed at the very beginning of this file for easier maintenance, thus commented out here.

```
11 <*package>
12 %\NeedsTeXFormat{LaTeX2e}
13 %\ProvidesPackage{tracefnt}[??/??/?? v?.??]
14 %
15 </package>
```

The `debug` module makes use of commands contained in a special package file named `trace.sty`.<sup>34</sup>

```
16 <+debug> \input trace.sty
```

### 4 Handling Options

`\tracingfonts` Here is the definition of the integer register for the font trace. As a default in a package file we use 1 to give error messages if fonts are substituted. If this code is used for debugging or tracing reasons in the format file (i.e. in `fam.dtx`) we use 0 as the default. But if no font trace is used we build a definition that will produce a warning message.

```
17 <*2ekernel>
18 \message{NFSS tracing,}
19 \def\tracingfonts{%
20   \@font@warning{Command \noexpand\tracingfonts
21     not provided.\MessageBreak
22     Use the ‘tracefnt’ package.\MessageBreak Command found:}%
23   \count@}
24 </2ekernel>
```

The `\count@` in the line above will remove the number after `\tracingfonts`. Note that this definition will be overwritten by the next line if one of these modules are included.

```
25 <*package, trace, debug>
26 \newcount\tracingfonts
27 \tracingfonts=0
28 </package, trace, debug>
```

*(End of definition for \tracingfonts.)*

The option `errorshow` turns off all warnings so that only real errors are shown. `warningshow` corresponds to the NFSS default (when `tracefnt` is not loaded). `info` is the default for this package here; and `debugshow`, `loading`, and `pausing` extend the amount of information even further.

```
29 <*package>
30 \DeclareOption{errorshow}{%
31   \def\@font@info#1{%
32     \GenericInfo{(Font)\@spaces\@spaces\@spaces\space\space}%
```

---

<sup>34</sup>This package is not in distribution at the moment (and probably doesn't any longer work). Think of this part of the code as being historical artifacts.

```

33             {LaTeX Font Info: \space\space\space#1}}%
34     \def\@font@warning#1{%
35         \GenericInfo{(Font)\@spaces\@spaces\@spaces\space\space}%
36             {LaTeX Font Warning: #1}}%
37     }
38 \DeclareOption{warningshow}{%
39     \def\@font@info#1{%
40         \GenericInfo{(Font)\@spaces\@spaces\@spaces\space\space}%
41             {LaTeX Font Info: \space\space\space#1}}%
42     \def\@font@warning#1{%
43         \GenericWarning{(Font)\@spaces\@spaces\@spaces\space\space}%
44             {LaTeX Font Warning: #1}}%
45     }
46 \DeclareOption{infoshow}{%
47     \def\@font@info#1{%
48         \GenericWarning{(Font)\@spaces\@spaces\@spaces\space\space}%
49             {LaTeX Font Info: \space\space\space#1}}%
50     \def\@font@warning#1{%
51         \GenericWarning{(Font)\@spaces\@spaces\@spaces\space\space}%
52             {LaTeX Font Warning: #1}}%
53     }
54 \DeclareOption{loading}{%
55     \tracingfonts\tw@
56 }
57 \DeclareOption{debugshow}{%
58     \ExecuteOptions{infoshow}%
59     \tracingfonts\thr@@
60 }
61 \DeclareOption{pausing}{%
62     \def\@font@warning#1{%
63         \GenericError
64             {(Font)\@spaces\@spaces\@spaces\space\space}%
65             {LaTeX Font Warning: #1}%
66             {See the LaTeX Companion for details.}%
67             {I'll stop for every LaTeX Font Warning because
68              you requested\MessageBreak the 'pausing' option
69              to the tracefnt package.}}%
70     }

```

We make `infoshow` the default, which in turn defines `\font@warning` and `\font@info`.

```

71 \ExecuteOptions{infoshow}
72 \ProcessOptions
73 \endpackage

```

We also need a default definition inside the kernel:

```

74 \if2ekernel
75 \def\@font@info#1{%
76     \GenericInfo{(Font)\@spaces\@spaces\@spaces\space\space}%
77         {LaTeX Font Info: \space\space\space#1}}%
78 \def\@font@warning#1{%
79     \GenericWarning{(Font)\@spaces\@spaces\@spaces\space\space}%
80         {LaTeX Font Warning: #1}}%
81 \fi

```

## 5 Macros common to fam.tex and tracefmt.sty

In the first versions of `tracefmt.dtx` some macros of `fam.dtx`<sup>35</sup> were redefined to include the extra tracing information. Now these macros are all defined in this file (i.e. removed from `fam.dtx`) and different production versions can be obtained simply by specifying a different set of modules to include when generating `lftss.dtx`.

### 5.1 General font loading

`\extract@font` This macro organizes the font loading. It first calls `\get@external@font` which will return in `\external@font` the name of the external font file (the `.tfm`) as it was determined by the NFSS tables.

```
82 <*2ekernel|package>
83 \def\extract@font{%
84     \get@external@font
```

Then the external font is loaded and assigned to the font identifier stored inside `\font@name` (for this reason we need `\expandafter`).

```
85     \global\expandafter\font\font@name\external@font\relax
```

When tracing we typeout the internal and external font name.

```
86 <*trace>
87     \ifnum \tracingfonts >\@ne
88     \@font@info{External font '\external@font'
89                 loaded as\MessageBreak \font@name}\fi
90 </trace>
```

Finally we call the corresponding “loading action” macros to finish things. First the font is locally selected to allow the use of `\font` inside the loading action macros.

```
91     \font@name \relax
```

The next two lines execute the “loading actions” for the family and then for the individual font shape.

```
92     \csname \f@encoding+\f@family\endcsname
93     \csname\curr@fontshape\endcsname
94     \relax
95     }
96 </2ekernel|package>
```

The `\relax` at the end needs to be explained. This is inserted to prevent `TEX` from scanning too far when it is executing the replacement text of the loading code macros.

*(End of definition for `\extract@font`.)*

`\get@external@font` This function tries to find an external font name. It will place the name into the macro `\external@font`. If no font is found it will return the one that was defined via `\DeclareErrorFont`.

```
97 <*2ekernel>
98 \def\get@external@font{%
```

We don’t know the external font name at the beginning.

```
99     \let\external@font\@empty
100     \edef\font@info{\expandafter\expandafter\expandafter\string
101                     \csname \curr@fontshape \endcsname}%
102     \try@size@range
```

---

<sup>35</sup>This file is currently not distributed in documented form. Its code is part of `lftss.dtx`.

If this failed, we'll try to substitute another size of the same font. This is done by the `\try@size@substitution` macro. It “knows about” `\do@extract@font`, `\font@name`, `\f@size`, and so on.

```

103 \ifx\external@font\@empty
104 \try@size@substitution
105 \ifx\external@font\@empty
106 \latex@error{Font \expandafter \string\font@name\space
107 not found}\@eha
108 \error@fontshape
109 \get@external@font
110 \fi\fi
111 }
112 \endkernel

```

(End of definition for `\get@external@font`.)

```

113 <*2ekernel | latexrelease | package>
114 <latexrelease> \IncludeInRelease{2021/06/01}%
115 <latexrelease> {\selectfont}{Add hook to \selectfont}%

```

`\selectfont` The macro `\selectfont` is called whenever a font change must take place.

```

116 \DeclareRobustCommand\selectfont
117 {%

```

When `debug` is specified we actually want something like ‘undebug’. The font selection is now stable so that using `\tracingall` on some other macros will show us a lot of unwanted information about font loading. Therefore we disable tracing during font loading as long as `\tracingfonts` is less than 4.

```

118 <+debug> \pushtracing
119 <+debug> \ifnum\tracingfonts<4 \tracingoff
120 <+debug> \else \tracingon\p@selectfont \fi

```

If `\baselinestretch` was redefined by the user it will not longer match its internal counterpart `\f@linespread`. If so we call `\set@fontsize` to prepare `\size@update`.

```

121 \ifx\f@linespread\baselinestretch \else
122 \set@fontsize\baselinestretch\f@size\f@baselineskip \fi

```

The series and shape updates are only prepared by `\fontseries` and `\fontshape` but not executed until after we are ready to change the font face. This way they happen after a possibly new family is set which is important because they look at the available font faces in that family and alter the selection based on availability. Several calls to `\fontseries` or `\fontshape` are delayed in the order in which they appear, so that by switching them one can work around missing intermediate font faces and avoid substitutions.

We first attempt to do the merge without any substitution. As we might end up with a non-existing font face we may have to restart and therefore save the current values of `\f@series` and `\f@shape` before the merge.

But first we make a quick test to see if there are any delayed actions, because if not it is pointless to make all the assignments and try loading a missing fontshape.

```

123 \ifx\delayed@f@adjustment\@empty
124 \else
125 \let\f@shape@savd\f@shape
126 \let\f@series@savd\f@series

```

Then we run the delayed adjustments (which use the `\..@without@substitution` commands):

```
127      \delayed@f@adjustment
```

We then check if the resulting combination is valid but for this we have to make sure that the appropriate `.fd` is loaded if that hasn't happened so far.

```
128      \maybe@load@fontshape
```

```
129      \ifcsname \f@encoding/\f@family/\f@series/\f@shape \endcsname
```

If this macro is defined then we are good and no further action is necessary.

Otherwise the combination is not valid, so we redo the merge but this time with substitutions.

```
130      \else
```

```
131          \let\f@shape\f@shape@saved
```

```
132          \let\f@series\f@series@saved
```

```
133          \let\delayed@merge@font@shape\merge@font@shape
```

```
134          \let\delayed@merge@font@series\merge@font@series
```

```
135          \delayed@f@adjustment
```

```
136          \let\delayed@merge@font@shape\merge@font@shape@without@substitution
```

```
137          \let\delayed@merge@font@series\merge@font@series@without@substitution
```

```
138      \fi
```

Now the series and shape values are updated and we clear `\delayed@f@adjustment`. This is important because on the next execution of `\selectfont` we should not mistakenly redo the delayed actions if there wasn't any series or shape change.

```
139      \let\delayed@f@adjustment\@empty
```

```
140      \fi
```

If the series was forced we should now cancel that in case the next series change is done with some low-level setting to `\f@series`.

```
141      \@forced@seriesfalse
```

Then we generate the internal name of the font by concatenating *family*, *series*, *shape*, and current *size*, with slashes as delimiters between them. This is much more readable than standard L<sup>A</sup>T<sub>E</sub>X's `\twbf`, etc. We define `\font@name` globally, as always. The reason for this is explained later on.

```
142      \xdef\font@name{%
```

```
143          \csname\curr@fontshape/\f@size\endcsname}%
```

We call the macro `\pickup@font` which will load the font if necessary.

```
144      \pickup@font
```

Then we select the font.

```
145      \font@name
```

After switching fonts we run a hook, so that packages can make last minute alterations based on the new font (originally provided in `every` but using a different interface).

```
146      \UseHook{selectfont}%
```

Finally we call `\size@update`. This macro is normally empty but will contain actions (like setting the `\baselineskip`) that have to be carried out when the font size, the base `\baselineskip` or the `\baselinestretch` have changed.

```
147      \size@update
```

A similar function is called to handle anything related to encoding updates. This one is changed from `\relax` by `\fontencoding`.

```
148 \enc@update
```

Just before ending this macro we have to pop the tracing stack if it was pushed before.

```
149 <+debug> \poptracing
150 }
```

(End of definition for `\selectfont`.)

**selectfont** Declare the hook used in `selectfont` in the kernel, but not inside the `tracefnt` package.

```
151 <-trace> \NewHook{selectfont}
```

(End of definition for `selectfont`.)

If `\tracingfonts` is greater than 2 we also show the font switch inside `\selectfont`. We do this by adding this code to the hook in the `tracefnt` package: macro might redefine `\font@name`.

```
152 <*trace>
153 \AddToHook{selectfont}
154   {\ifnum \tracingfonts>\tw@
155     \font@info{Switching to \font@name}\fi}
156 </trace>
157 </2ekernel | latexrelease | package>
158 <latexrelease> \EndIncludeInRelease
```

With `\selectfont` having different definitions in different kernels we also have to provide them in the `tracefnt` package to support rollback. In packages that works a bit differently and therefore we have to provide an empty block there.

```
159 <package> \IncludeInRelease{2021/06/01}%
160 <package> \selectfont{\Add hook to \selectfont}%
161 <package> \EndIncludeInRelease

162 <latexrelease | package> \IncludeInRelease{0000/00/00}%
163 <latexrelease | package> \selectfont{\Add hook to \selectfont}%
164 <latexrelease | package>
165 <latexrelease | package> \DeclareRobustCommand\selectfont
166 <latexrelease | package>   {%
167 <latexrelease | package>     \ifx\f@linespread\baselinestretch \else
168 <latexrelease | package>       \set@fontsize\baselinestretch\f@size\f@baselineskip \fi
169 <latexrelease | package>     \xdef\font@name{%
170 <latexrelease | package>       \csname\curr@fontshape/\f@size\endcsname}%
171 <latexrelease | package>     \pickup@font
172 <latexrelease | package>     \font@name
173 <latexrelease | package>     \size@update
174 <latexrelease | package>     \enc@update
175 <latexrelease | package>   }
176 <latexrelease | package>
177 <latexrelease | package> \EndIncludeInRelease
```

**\set@fontsize** The macro `\set@fontsize` does the actual work. First it assigns new values to `\f@size`, `\f@baselineskip` and `\f@linespread`.

```
178 <*2ekernel | package>
179 \def\set@fontsize#1#2#3{%
180   \@defaultunits\@tempdimb#2pt\relax\@nnil
```

```

181 \edef\f@size{\strip@pt\@tempdimb}%
182 \@defaultunits\@tempskipa#3pt\relax\@nnil
183 \edef\f@baselineskip{\the\@tempskipa}%
184 \edef\f@linespread{#1}%

```

For backward compatibility and for later testing within `\selectfont` the internal value of `\f@linespread` is passed back to `\baselinestretch`.

```

185 \let\baselinestretch\f@linespread

```

Additional processing will happen within `\selectfont`. For this reason the macro `\size@update` (which will be called in `\selectfont`) will be defined to be:

```

186 \def\size@update{%

```

First calculate the new `\baselineskip` and also store it in `normalbaselineskip`

```

187 \baselineskip\f@baselineskip\relax
188 \baselineskip\f@linespread\baselineskip
189 \normalbaselineskip\baselineskip

```

then to set up a new `\strutbox`

```

190 \setbox\strutbox\hbox{%
191 \vrule\@height.7\baselineskip
192 \@depth.3\baselineskip
193 \@width\z@}%

```

We end with a bit of tracing information.

```

194 \<trace>
195 \ifnum \tracingfonts>\tw@
196 \ifx\f@linespread\@empty
197 \let\reserved@a\@empty
198 \else
199 \def\reserved@a{\f@linespread x}%
200 \fi
201 \@font@info{Changing size to \f@size/\reserved@a
202 \f@baselineskip}%
203 \aftergroup\type@restoreinfo \fi
204 \</trace>

```

When all this is processed `\size@update` redefines itself to `\relax` so that in later calls of `\selectfont` no extra code will be executed.

```

205 \let\size@update\relax}%
206 }

```

Instead of defining this macro internally we might speed things up by placing the code into a separate macro and use `\let`!

*(End of definition for \set@fontsize.)*

**\size@update** Normally this macro does nothing; it will be redefined by `\set@fontsize` to initiate an update.

```

207 \let\size@update\relax

```

*(End of definition for \size@update.)*

`\type@restoreinfo` This macro produces some info when a font size and/or baseline change will get restored.

```

208 <*trace>
209   \def\type@restoreinfo{%
210     \ifx\f@linespread\@empty
211       \let\reserved@a\@empty
212     \else
213       \def\reserved@a{\f@linespread x}%
214     \fi
215     \@font@info{Restoring size to
216                \f@size/\reserved@a\f@baselineskip}}
217 </trace>

```

(End of definition for `\type@restoreinfo`.)

`\glb@settings` The macro `\glb@settings` globally selects all math fonts for the current size if necessary.  
`\glb@currsz`

```

218 \def\glb@settings{%

```

When `\glb@settings` gains control a size change was requested and all previous font assignments need to be replaced. Therefore the old values of the fonts are no longer needed. For every *math group* the new assignments are appended to `\math@fonts`. But this happens only if the `\math@fonts` switch is set to true. However, we always set up the correct math sizes for script and scriptscript fonts since they may be needed even if we don't set up the whole math machinery.

Here we set the math size, script size and scriptscript size. If the `S@...` macro is not defined we have to first calculate the three sizes.

```

219   \expandafter\ifx\csname S@\f@size\endcsname\relax
220     \calculate@math@sizes
221   \fi

```

The effect of this is that `\calculate@math@sizes` may or may not define the `S@...` macro. In the first case the next time the same size is requested this macro is used, otherwise `\calculate@math@sizes` is called again. This also sets the `\math@fonts` switch. If it is true we must switch the math fonts.

```

222   \csname S@\f@size\endcsname
223   \ifmath@fonts
224 <*trace>
225     \ifnum \tracingfonts>\tw@
226       \@font@info{Setting up math fonts for
227                  \f@size/\f@baselineskip}\fi
228 </trace>

```

Inside a group we execute the macro for the current math *version*. This sets `\math@fonts` to a list of `\textfont...` assignments. `\getanddefine@fonts` (which may be called at this point) needs the `\escapechar` parameter to be set to `-1`.

```

229   \begingroup
230     \escapechar\m@ne
231     \csname mv@\math@version \endcsname

```

Then we set `\globaldefs` to 1 so that all following changes are done globally. The math font assignments recorded in `\math@fonts` are executed and `\glb@currsz` is set equal to `\f@size`. This signals that the fonts for math in this size are set up.

```

232     \globaldefs\@ne
233     \math@fonts

```

2. Whenever we start a formula we compare its value with the local variable `\f@size` that describes the current text font size.
3. If both are the same we assume that we can use the current math font setup without adjustment.
4. If they differ we call `\glb@settings` which changes the math font setup and updates `\glb@currsz`.
  - (a) If we are recursively inside another formula (`\if@inmath`) we ensure that `\glb@settings` is executed again in the outer formula, so that the old setup is automatically restored.
  - (b) Otherwise, we set the switch `@inmath` locally to `true` so that all nested formulae will be able to detect that they are nested in some outer formula.

The above algorithm has the following features:

- For sizes which are not containing any formula no math setup is done. Compared to the original algorithm of NFSS this results in the following savings:
  - No unnecessary loading of math fonts for sizes that are not used to typeset any math formulae (explicit or implicit ones).
  - No time overhead due to unnecessary changes of the math font setup on entrance and exit of the text font size.
- Math font setup changes for top-level formulae will survive (there is no restoration after the formula) thus any following formula in the same size will be directly typesettable. Compared to original implementation in NFSS2 the new algorithm has the overhead of one test per formula to see if the current math setup is valid (in the original algorithm the setup was always valid, thus no test was necessary).
- In nested formulae the math font setup is restored in the outer formula by a series of `\aftergroup` commands and checks. Compared to the original algorithm this involves additional checks ( $2 \times \langle \text{non-math levels} \rangle$  per inner formula).

### 5.2.2 Code for math font size setting

`\check@mathfonts` In the `\check@mathfonts` macros we implement the steps 2 to 4 except that instead of a switch the macro `\init@restore@glb@settings` is used.

```

251 <*2kernel | package>
252 \def\check@mathfonts{%
253   \ifx \glb@currsz \f@size
254   <*trace>
255     \ifnum \tracingfonts>\thr@@
256       \@font@info{*** MATH: no change \f@size\space
257         curr/global (\curr@math@size/\glb@currsz)}\fi
258   </trace>
259   \else
260   <*trace>
261     \ifnum \tracingfonts>\thr@@
262       \@font@info{*** MATH: setting up \f@size\space
263         curr/global (\curr@math@size/\glb@currsz)}\fi
264   </trace>

```

```

265     \glb@settings
266     \init@restore@glb@settings
267   \fi
268   \let\curr@math@size\font@size
269   \def\init@restore@glb@settings{\aftergroup\restglb@settings}%
270 }

```

(End of definition for \check@mathfonts.)

**\init@restore@glb@settings** This macro does by default nothing but get redefined inside \check@mathfonts to initiate fontsize restoring in nested formulas.

```

271 <-trace>\let\init@restore@glb@settings\relax
272 <*trace>
273 \def\init@restore@glb@settings{%
274     \ifnum \tracingfonts>\thr@@
275     \font@info{*** MATH: no resetting (not in
276         nested math)}\fi
277 }
278 </trace>

```

(End of definition for \init@restore@glb@settings.)

**\restglb@settings** This macro will be executed the first time after the current formula.

```

279 \def\restglb@settings{%
280 <*trace>
281     \ifnum \tracingfonts>\thr@@
282     \font@info{*** MATH: restoring}\fi
283 </trace>
284     \begingroup
285     \let\font@size\curr@math@size
286     \ifx\glb@currsz \font@size
287 <*trace>
288     \ifnum \tracingfonts>\thr@@
289     \font@info{*** MATH: ... already okay (\font@size)}\fi
290 </trace>
291     \else
292 <*trace>
293     \ifnum \tracingfonts>\thr@@
294     \font@info{*** MATH: ... to \font@size}\fi
295 </trace>
296     \glb@settings
297     \fi
298   \endgroup
299 }

```

(End of definition for \restglb@settings.)

### 5.2.3 Other code for math

**\use@mathgroup** The \use@mathgroup macro should be used in user macros to select a math group. Depending on whether or not the margid option is in force it has two or three arguments. For this reason it should be called as the last macro.

First we test if we are inside math mode since we don't want to apply a useless definition.

```

300 \def\use@mathgroup#1#2{\relax\ifmmode

```

```

301 <*trace>
302   \ifnum \tracingfonts>\tw@
303     \count@#2\relax
304     \@font@info{Using \noexpand\mathgroup
305               (\the\count@) #2}\fi
306 </trace>

```

If so we first call the ‘=’ macro (i.e. argument three) to set up special things for the selected math group. Then we call `\mathgroup` to select the group given by argument two and finally we place `#1` (i.e., the argument of the `<math alphabet identifier>`) at the end. This part of the code is surrounded by two commands which behave like `\begingroup` and `\endgroup` if we want `<math alphabet identifier>`s but will expand into `\@empty` if we want simply switches to a new math group. Since argument number 2 may be a digit instead of a control sequence we add a `\relax`. Otherwise something like `\mit{1}` would switch to math group 11 (and back) instead of printing an oldstyle 1.

```

307   \math@bgroup
308     \expandafter\ifx\csname M@\f@encoding\endcsname#1\else
309     #1\fi
310     \mathgroup#2\relax

```

Before we reinsert the swallowed token (arg. three) into the input stream, in the case that the `<math alphabet identifier>` isn’t called in math mode, we remove the `\fi` with the `\expandafter` trick. This is necessary if the token is actually an macro with arguments. In such a case the `\fi` will be misinterpreted as the first argument which would be disastrous.

```

311   \expandafter\math@egroup\fi}%

```

The surrounding macros equal `\begingroup` and `\endgroup`. But using internal names makes it possible to overwrite their meaning in certain cases. This is for example used in  $\mathcal{MS}$ -TeX macros for placing accents.

(End of definition for `\use@mathgroup`.)

`\math@egroup` If the `margid` option is in force (which can be tested by looking at the definition of `\math@bgroup`) we change the `\math@egroup` command a bit to display the current `<math group number>` after it closes the scope of `<math alphabet>` with `\endgroup`.

```

312 <*trace>
313   \ifx\math@bgroup\bgroup
314     \def\math@egroup#1{#1\egroup
315       \ifnum \tracingfonts>\tw@
316         \@font@info{Restoring \noexpand\mathgroup
317               (\ifnum\mathgroup=\m@ne default\else \the\mathgroup \fi)%
318               }\fi}
319   \fi
320 </trace>

```

(End of definition for `\math@egroup`.)

`\getanddefine@fonts` `\getanddefine@fonts` has two arguments: the `<math group number>` and the *family/series/shape* name as a control sequence.

```

321 \def\getanddefine@fonts#1#2{%

```

First we turn of tracing when `\tracingfonts` is less than 4.

```

322 <+debug> \pushtracing
323 <+debug> \ifnum\tracingfonts<4 \tracingoff
324 <+debug> \else \tracingon\getanddefine@fonts \fi

325 <*trace>
326 \ifnum \tracingfonts>\tw@
327 \count@#1\relax
328 \font@info{\noexpand\mathgroup (\the\count@) #1 :=\MessageBreak
329 \string#2 \tf@size/\sf@size/\ssf@size}\fi
330 /trace>

```

We append the current `\tf@size` to `#2` to obtain the font name.<sup>36</sup> Again, `font@name` is defined globally, for the reasons explained in the description of `\wrong@fontshape`.

```

331 \xdef\font@name{\csname \string#2/\tf@size\endcsname}%

```

Then we call `\pickup@font` to load it if necessary. We remember the internal name as `\textfont@name`.

```

332 \pickup@font \let\textfont@name\font@name

```

Same game for `\scriptfont` and `\scriptscriptfont`, but here we additionally transform the fontname through `\transform@scriptfont` to allow different family names in math scripts.

```

333 \xdef\font@name{\csname \transform@scriptfont {sf}{#2}/\sf@size\endcsname}%
334 \pickup@font \let\scriptfont@name\font@name
335 \xdef\font@name{\csname \transform@scriptfont {ssf}{#2}/\ssf@size\endcsname}%
336 \pickup@font

```

Then we append the new `\textfont...` assignments to the `\math@fonts`.

```

337 \edef\math@fonts{\math@fonts
338 \textfont#1\textfont@name
339 \scriptfont#1\scriptfont@name
340 \scriptscriptfont#1\font@name}%

```

Just before ending this macro we have to pop the tracing stack if it was pushed before.

```

341 <+debug> \poptracing
342 }

```

(End of definition for `\getanddefine@fonts`.)

`\transform@scriptfont` `\transform@scriptfont` has two arguments: the name of the script size we transform the font for (always `sf` or `ssf`) and the *family/series/shape* name as a `csname`. It expands to a new *family/series/shape* name which will be used for this script. For this `\transform@scriptfont` mostly delegates to `\__nfss_transform_scriptfont:nw`, which searches for a replacement marker `\__nfss_mapped_scriptfont_family_⟨scriptsize⟩_⟨encoding⟩` with a remapped encoding and family.

```

343 \ExplSyntaxOn
344 \cs_set:Npn \transform@scriptfont #1 #2 {
345 \exp_last_unbraced:Nno
346 \__nfss_transform_scriptfont:nw
347 {#1}
348 {\token_to_str:N #2}
349 }

```

<sup>36</sup>One might ask why this expansion does not generate a macro name that starts with an additional `\` character. The solution is that `\escapechar` is set to `-1` before `\getanddefine@fonts` is called.

```

350 \cs_set:Npn \__nfss_transform_scriptfont:nw #1 #2 / #3 / {
351   \cs_if_exist_use:cF { __nfss_mapped_scriptfont_family_ #1 _ #2 / #3 } { #2 / #3 }
352   /
353 }

```

(End of definition for `\transform@scriptfont`.)

`\DeclareMathScriptfontMapping` `\DeclareMathScriptfontMapping` can be used to define replacement font families which will be used for math subscripts or subsubscripts when a specific font family is used as the main math font. For this `\DeclareMathScriptfontMapping` takes three pairs of encoding and family names as arguments: The first pair identifies the base font for which associated script and scriptscript variants should be declared. The second pair describes the family which should be used as scriptfonts (e.g. in subscripts). Finally the third pair describes the family which should be used as scriptscriptfonts (e.g. in nested subscripts).

```

354 \cs_set:Npn \DeclareMathScriptfontMapping #1 #2 #3 #4 #5 #6 {
355   \cs_set:cpn { __nfss_mapped_scriptfont_family_sf_ #1 / #2 } { #3 / #4 }
356   \cs_set:cpn { __nfss_mapped_scriptfont_family_ssf_ #1 / #2 } { #5 / #6 }
357 }
358 \ExplSyntaxOff
359 </2ekernel|package>

```

(End of definition for `\DeclareMathScriptfontMapping`.)

## 6 Scaled font extraction

`\ifnot@nil` We begin with a simple auxiliary macro. It checks whether its argument is the token `\@nil`. If so, it expands to `\@gobble` which discards the following argument, otherwise it expands to `\@firstofone` which reproduces its argument.

```

360 <*2ekernel>
361 \def\ifnot@nil#1{\def\reserved@a{#1}%
362   \ifx\reserved@a\@nnil \expandafter\@gobble
363   \else \expandafter\@firstofone\fi}

```

(End of definition for `\ifnot@nil`.)

`\remove@to@nnil` Three other auxiliary macros will be needed in the following: `\remove@to@nnil` gobbles up everything up to, and including, the next `\@nnil` token, and `\remove@angles` and `\remove@star` do the same for the character `>` and `*`, respectively, instead of `\@nnil`.

```

364 \def\remove@to@nnil#1\@nnil{}
365 \def\remove@angles#1>{\set@simple@size@args}
366 \def\remove@star#1*{#1}

```

(End of definition for `\remove@to@nnil`, `\remove@angles`, and `\remove@star`.)

`\extract@sizefn` This macro takes a size specification and parses it into size function and the optional and mandatory arguments.

```

367 \def\extract@sizefn#1*#2\@nil{%
368   \if>#2>\set@size@funct@args#1\@nil
369   \let\sizefn@info\@empty
370   \else\expandafter\set@size@funct@args\remove@star#2\@nil
371   \def\sizefn@info{#1}\fi
372 }

```

(End of definition for `\extract@sizefn`.)

`\try@simple@size` This function tries to extract the given size (specified by `\f@size`) for the requested font shape. The font information must already be present in `\font@info`. The central macro that does the real work is `\extract@fontinfo`. We will first give a simple example how this macro works, and describe it in full generality later.

Assume that the requested parameters are: *encoding scheme* ‘OT1’, *family* ‘cm’, *series* ‘sansserif’, *shape* ‘normal’, and *size* ‘12’. The corresponding font definitions have already been extracted from the macro `\OT1/cm/sansserif/normal` and stored in `font@info`. (Otherwise `\extract@fontinfo` doesn’t get called.) This information consists of a token list made of characters of category code 12 of the form

```
<10*>cmss10<12*>cmss12<17*>cmss17
```

For reasonable packages one usually needs more sizes but this is sufficient to get the flavour. We will define a macro `\extract@fontinfo` to find the external font name (‘cmss12’) for us:

```
\def\extract@fontinfo#1<12*#2>#3<#4\@nnil{%
  \set@simple@size@args#3<#4\@nnil
  \execute@size@function{#2}}}
```

so that when it gets called via

```
\extract@fontinfo<10*>cmss10<12*>cmss12<17*>cmss17\@nnil
```

#1 will contain all characters before `<12*>`, #2 will be empty, #3 will be exactly `cmss12`, and #4 will be `17>cmss17`. The expansion is therefore

```
\set@simple@size@args cmss12<17*>cmss17\@nnil
\execute@size@function{}
```

This means: the default (empty) size function will be executed, with its optional argument set to empty and its mandatory argument set to `cmss12` by `\set@simple@size@args`. As we discussed earlier, the effect of the default size function is to load the given external font (`cmss12`) at the specified size (12)—which is exactly what was intended.

But this is only part of the whole story. It may be that the size requested does not occur in the token list `\font@info`. And the simple definition of `\extract@fontinfo` we gave above does not allow to specify give more than one size specification in front of the external font name.

Let’s address these two problems separately. The first one is solved with the following trick: We define `\extract@fontinfo` as follows:

```
\def\extract@fontinfo#1<12*#2>#3<#4\@nnil{%
  \ifnot@nil{#3}%
  {\set@simple@size@args#3<#4\@nnil
   \execute@size@function{#2}}%
  }%}
```

How does this work? We call `\extract@fontinfo` via

```
\expandafter\extract@fontinfo\font@info<12*>\@nil\@nnil
```

i.e. by appending `<12*>\@nil<\@nnil`. If the size ('12' in this case) appears in `\font@info` everything works as explained above, the only difference being that argument #4 of `\extract@fontinfo` additionally gets the tokens `<12*>\@nil<\@nnil`. However, if the size is not found everything up to the final `<12*>` is in argument #1, #3 gets `\@nil`, and #2 and #4 are empty. The macro `\ifnot@nil` will discard the calls to `\set@simple@size@args` and `execute@size@function`, and hence `\font@info` will continue to be equal to `\@empty`. This means that no simple size specification matching the requested size could be found.

The second problem (more than one simple size specification for one external font name) will be addressed in `\set@simple@size@args` below.

The macros are hidden inside other control sequences so that we have to build `\extract@fontinfo` in several steps.

So here's the actual definition of `\extract@font` in `\try@simple@size`.

```
373 % % this could be replaced by \try@size@range making the subst slower!
374 \def\try@simple@size{%
```

`\reserved@a` is made an abbreviation for the head of the definition of the macro `\extract@fontinfo`.

```
375 \def\reserved@a{\def\extract@fontinfo####1}%
```

Now we can define `\extract@fontinfo`. Here we handle a small but convenient variation: in case of the default (empty) size function it is allowed to omit the `*` character.

```
376 \expandafter\reserved@a\expandafter<\f@size>##2<##3\@nnil{%
377 \ifnot@nil{##2}%
378 {\set@simple@size@args##2<##3\@nnil
379 \execute@size@function\sizefn@info
380 }%}
```

Now we call `\extract@fontinfo`. Note the `<\@nil` tokens at the end.

```
381 \expandafter\expandafter
382 \expandafter\extract@fontinfo\expandafter\font@info
383 \expandafter<\f@size>\@nil<\@nnil
384 }
```

*(End of definition for \try@simple@size.)*

`\set@simple@size@args` As promised above, the macro `\set@simple@size@args` will handle the case of several size specifications in a row. If another size specification follows, the very first token of its argument list is the character `<`. By starting the definition as follows,

```
385 \def\set@simple@size@args#1<{%
```

parameter #1 is empty in this case, and contains the size function's arguments otherwise. We distinguish these two cases (Note that the character `<` cannot appear in #1) by calling `\remove@angles` for empty #1 and `\extract@sizefn` otherwise. In the latter case we have to take care of the remaining character tokens and discard them. This is done by `\remove@to@nnil`. Note also the use of Kabelschacht's method.

```
386 \if<#1<%
387 \expandafter\remove@angles
388 \else
389 \extract@sizefn#1*\@nil
390 \expandafter\remove@to@nnil
391 \fi}
```

(End of definition for \set@simple@size@args.)

Now, we are through with the case of a simple size, except for calling the size function. This will be handled later, as it is the same mechanism for all types of size specification. We will now proceed to macros for extraction of size range specification.

**\extract@rangefontinfo** \extract@rangefontinfo goes through a font shape definition in the input until it recognizes the tokens <\@nil->. It looks for font ranges with font size functions. It's operation is rather simple: it discards everything up to the next size specification and passes this on to \is@range for inspection. The specification (parameter #2) is inserted again, in case it is needed later.

```
392 \def\extract@rangefontinfo#1<#2>{%
393     \is@range#2->\@nil#2>}
```

(End of definition for \extract@rangefontinfo.)

**\is@range** \is@range is again a sort of dispatcher macro: if the size specification it is looking at is not a range specification it discards it and calls \extract@rangefontinfo to continue the search. Otherwise it calls \check@range to check the requested size against the specified range.

From the way \is@range is called inside \extract@rangefontinfo we see that #2 is the character > if the size specification found is a simple one (that does not contain a - character). This is checked easily enough and \extract@rangefontinfo called again. Note that the extra tokens inserted after the \@nil in the call to \is@range appear at the beginning of the first argument to \extract@rangefontinfo and are hence ignored.

```
394 \def\is@range#1-#2\@nil{%
395     \if>#2\expandafter\check@single\else
396     \expandafter\check@range\fi}
```

(End of definition for \is@range.)

**\check@range** \check@range takes lower bound as parameter #1, upper bound as #2, size function as #3 and the size function's arguments as #4. If #3 is the special token \@nil \font@info is exhausted and we can stop searching.

```
397 \def\check@range#1-#2>#3<#4\@nnil{%
398     \ifnot@nil{#3}{%
```

If #3 wasn't \@nil we have a range. We start by assuming that we have to recurse. Note that we have to reinsert an < as it was already removed by scanning.

```
399     \def\reserved@f{\extract@rangefontinfo<#4\@nnil}%
```

We have to make sure that both boundaries are present, if not we have to set them. Here we check the upper bound. If \upper@bound is zero after the assignment we set it to \maxdimen (upper open range). We need to use a <dimen> register for the scan since we may have a decimal number as the boundary.

```
400     \upper@bound0#2\p@
401     \ifdim\upper@bound=\z@ \upper@bound\maxdimen\fi
```

Now we check the upper boundary against \f@size. If it is larger or equal than \f@size this range is no good and we have to recurse.

```
402     \ifdim \f@size \p@<\upper@bound
```

Otherwise we have to check the lower bound. This time it is not necessary to scan the boundary value into a register because if it is empty we get zero as desired. We could even omit the 0 which would result in 1pt as default lower boundary. If \f@size is smaller than the boundary we have to recurse.

```
403      \lower@bound0#1\p@
404      \ifdim \f@size \p@<\lower@bound
405      \else
```

If both tests are passed we can try executing the size function.

```
406      \set@simple@size@args#3<#4\@nnil
407      \execute@size@function\sizefn@info
```

If the function was successful it should have left an external font name in \external@font. We use this to see if we can stop scanning. Otherwise we recurse.

```
408      \ifx\external@font\@empty
409      \else
410      \let\reserved@f\@empty
411      \fi
412      \fi
413      \fi
414      \reserved@f}}
```

*(End of definition for \check@range.)*

**\lower@bound** We use two dimen registers \lower@bound and \upper@bound to store the lower and upper endpoints of the range we found.

```
415 \newdimen\lower@bound
416 \newdimen\upper@bound
```

*(End of definition for \lower@bound and \upper@bound.)*

**\check@single** \check@single takes the size as parameter #1, size function as #2 and the size function's arguments as #3. We can assume that there is always something in the pipeline since the very last entry is a faked range (see above).

```
417 \def\check@single#1>#2<#3\@nnil{%
```

We start by assuming that we have to recurse. Note that we have to reinsert an < as it was already removed by scanning.

```
418      \def\reserved@f{\extract@rangefontinfo<#3\@nnil}%
```

Now we check the size against \f@size. If it is not equal \f@size it is no good and we have to recurse.

```
419      \ifdim \f@size \p@=#1\p@
```

Otherwise if this test is passed we can try executing the size function.

```
420      \set@simple@size@args#2<#3\@nnil
421      \execute@size@function\sizefn@info
```

If the function was successful it should have left an external font name in \external@font. We use this to see if we can stop scanning. Otherwise we recurse.

```
422      \ifx\external@font\@empty
423      \else
424      \let\reserved@f\@empty
425      \fi
426      \fi
427      \reserved@f}
```

(End of definition for \check@single.)

**\set@size@funct@args** This macro sets the optional and mandatory arguments for a size function. If the optional argument is not present it is set to the empty token list. The mandatory argument is delimited by the token \@nil.

```

428 \def\set@size@funct@args{\@ifnextchar[%
429   \set@size@funct@args@\set@size@funct@args@[]]}
430 \def\set@size@funct@args@[#1]#2\@nil{%
431   \def\mandatory@arg{#2}%
432   \def\optional@arg{#1}}
433 \</2ekernel>

```

(End of definition for \set@size@funct@args and \set@size@funct@args@.)

**\DeclareSizeFunction** This function defines a new size function hiding the internal from the designer. The body of the size function may use \optional@arg and \mandatory@arg denoting the optional and mandatory argument that may follow the size specification <...>.

```

434 \<2ekernel>
435 \def\DeclareSizeFunction#1#2{\@namedef{s@fct@#1}{#2}}
436 \@onlypreamble\DeclareSizeFunction
437 \</2ekernel>

```

(End of definition for \DeclareSizeFunction.)

**\execute@size@function** This macro is very simple. The only point worth noting is that calling an undefined size function will do nothing (actually execute a \relax).

```

438 \<2ekernel | package>
439 \def\execute@size@function#1{%
440 \<trace>
441   \ifundefined{s@fct@#1}%
442     {\errmessage{Undefined font size function #1}%
443      \s@fct@}%
444     {\csname s@fct@#1\endcsname}%
445 \</trace>
446 \<-trace>   \csname s@fct@#1\endcsname
447 }
448 \</2ekernel | package>

```

(End of definition for \execute@size@function.)

**\try@size@range** This macro tries to find a suitable range for requested size (specified by \f@size) in \font@info. All the relevant action is done in \extract@rangefontinfo. All that needs to be done is to stuff in the token list in \font@info so that \extract@rangefontinfo can inspect it. Note the <-\*\@nil>< token at the end to stop scanning.

```

449 \<2ekernel>
450 \def\try@size@range{%
451   \expandafter\extract@rangefontinfo\font@info <-*\@nil>\@nnil
452 }

```

(End of definition for \try@size@range.)

**\try@size@substitution** This is the last thing that can be tried. If the desired \f@size is found neither among the simple size specifications nor in one of the ranges the whole list of size specifications is searched for a nearby simple size.

```

453 \gdef\try@size@substitution{%

```

First we do some initializations. `\@tempdimb` will hold the difference between the wanted size and the best solution found so far, so we initialise it with `\maxdimen`. The macro `\best@size` will hold the best size found, nothing found is indicated by the empty value.

```
454 \tempdimb \maxdimen
455 \let \best@size \@empty
```

Now we loop over the specification

```
456 \expandafter \try@simples \font@info <\number\@M>\@nil<\@nnil
457 }
```

*(End of definition for \try@size@substitution.)*

`\font@submax` The macro `\font@submax` records the maximal deviation from the desired size encountered so far. Its value is used in a warning message at `\end{document}`. The macro `\fontsubfuzz` contains the amount that will not cause terminal warnings (warnings still go into the transcript file).

```
458 \def\font@submax{0pt}
459 \def\fontsubfuzz{.4pt}
460 </2ekernel>
461 <+package>\def\fontsubfuzz{0pt}
```

*(End of definition for \font@submax and \fontsubfuzz.)*

`\try@simples` `\try@simples` goes through a font shape definition in the input until it recognizes the tokens `<*\@nil>`. It looks for simple sizes to determine the two closest sizes. It is assumed that simple sizes are in increasing order.

```
462 <*2ekernel>
463 \gdef\try@simples#1<#2>{%
464 \tryif@simple#2->\tryif@simple}
```

*(End of definition for \try@simples.)*

`\tryis@simple` `\tryis@simple` is similar to `\is@range`. If it sees a simple size, it checks it against the value of `\f@size` and sets `\lower@font@size` or `\higher@font@size`. In the latter case, it stops the iteration. By adding `<\number\@M>` at the end of the line we always have an end point. This is a hack which probably should be corrected.

First it checks whether it is finished already, then whether the size specification in question is a simple one.

```
465 \gdef\tryif@simple#1-#2\tryif@simple{%
```

Most common case for `\reserved@f` first:

```
466 \let \reserved@f \try@simples
467 \if>#2%
```

If so, it compares it to the value of `\f@size`. This is done using a dimen register since there may be fractional numbers.

```
468 \dimen@ #1\p@
469 \ifdim \dimen@<\@M\p@
```

If `\dimen@` is `\M\p@` we have reached the end of the fontspec (hopefully) otherwise we compare the value with `\f@size` and compute in `\@tempdimc` the absolute value of the difference between the two values.

```

470     \ifdim \f@size\p@<\dimen@
471         \@tempdimc \dimen@
472         \advance\@tempdimc -\f@size\p@
473     \else
474         \@tempdimc \f@size\p@
475         \advance\@tempdimc -\dimen@
476     \fi

```

The result is then compared with the smallest difference we have encountered, if the new value (in `\@tempdimc` is smaller) we have found a size which is a better approximation so we make it the `\best@size` and adjust `\@tempdimb`.

```

477     \ifdim \@tempdimc<\@tempdimb
478         \@tempdimb \@tempdimc
479         \def \best@size{#1}%
480     \fi

```

When we have reached the end of the fontspec we substitute the best size found (if any). We code this inline to save macro space; in the past this was done by a macro called `\subst@size`.

```

481     \else

```

This macro substitutes the size recorded in `\best@size` for the unavailable size `\f@size`. `\subst@size` `\font@submax` records the maximum difference between desired size and selected size in the whole run.

```

482 % \subst@size                %% coded inline
483 % \def\subst@size{%
484     \ifx \external@font\@empty
485         \ifx \best@size\@empty
486         \else
487             \ifdim \@tempdimb>\font@submax \relax
488             \xdef \font@submax {\the\@tempdimb}%
489         \fi
490         \let \f@user@size \f@size
491         \let \f@size \best@size
492         \ifdim \@tempdimb>\fontsubfuzz\relax
493             \@font@warning{Font\space shape\space
494                 '\curr@fontshape'\space in\space size\space
495                 <\f@user@size>\space not\space available\MessageBreak
496                 size\space <\f@size>\space substituted}%
497         \fi
498         \try@simple@size
499         \do@subst@correction
500     \fi
501 \fi
502 % %}

```

This brings us back into the main part of `\tryif@simple`. Finally we get rid of any rubbish left over on the input stack.

```

503     \let \reserved@f \remove@to@nnil
504     \fi
505 \fi

```

If it's a range iterate also.

```
506 \reserved@f}
```

(End of definition for `\tryis@simple` and `\subst@size`.)

## 6.1 Sizefunctions

In the following we define some useful size functions.

`\s@fct@` This is the default size function. Mandatory argument is an external font name, optional argument a scale factor. The font is scaled to `\f@size` if no optional argument is present, and to `\f@size` multiplied by the optional argument otherwise.

```
507 \DeclareSizeFunction{}\empty@sfcnt\@font@warning}
508 \DeclareSizeFunction{s}\empty@sfcnt\@font@info}

509 \def\empty@sfcnt#1{%
510     \@tempdimb \f@size\p@
511     \ifx\optional@arg\empty
512     \else
513         \@tempdimb \optional@arg\@tempdimb
514         #1{Font\space shape\space '\curr@fontshape'\space
515             will\space be\MessageBreak
516             scaled\space to\space size\space \the\@tempdimb}%
517     \fi
518     \edef\external@font{\mandatory@arg\space at\the\@tempdimb}}
```

(End of definition for `\s@fct@`.)

`\s@fct@gen` This size function generates the external name from the mandatory argument and the requested user size, and thus can be used for external names where the size is encoded in the font name. The optional argument a scale factor. The font is scaled to `\f@size` if no optional argument is present, and to `\f@size` multiplied by the optional argument otherwise.

```
519 \DeclareSizeFunction{gen}\gen@sfcnt\@font@warning}
520 \DeclareSizeFunction{sgen}\gen@sfcnt\@font@info}

521 \def\gen@sfcnt{%
522     \edef\mandatory@arg{\mandatory@arg\f@size}%
523     \empty@sfcnt}
```

(End of definition for `\s@fct@gen` and `\s@fct@sgen`.)

`\s@fct@genb` This size function is similar to `gen`, but for fonts where the size is encoded in the font name in centipoints, as in the DC fonts version 1.2. The font is scaled to `\f@size` if no optional argument is present, and to `\f@size` multiplied by the optional argument otherwise.

```
524 \DeclareSizeFunction{genb}\genb@sfcnt\@font@warning}
525 \DeclareSizeFunction{sgenb}\genb@sfcnt\@font@info}

526 \def\genb@sfcnt{%
527     \edef\mandatory@arg{\mandatory@arg\expandafter\genb@x\f@size..\@@}%
528     \empty@sfcnt}
```

(End of definition for `\s@fct@genb` and `\s@fct@sgenb`.)

`\genb@x` The auxiliary macros `\genb@x` and `\genb@y` are used to convert the `\f@size` into centi-points.

```
529 \def\genb@x#1.#2.#3\@@{\two@digits{#1}\genb@y#200\@@}
530 \def\genb@y#1#2#3\@@{#1#2}
```

*(End of definition for `\genb@x` and `\genb@y`.)*

`\s@fct@sub` This size function handles font substitution. The mandatory argument is a family/series/shape combination, the optional argument (if present) is ignored. The font encoding scheme cannot be changed. Therefore, the first thing we do is to prepend the encoding scheme.

```
531 \DeclareSizeFunction{sub}{\sub@sfcnt\@font@warning}
532 \DeclareSizeFunction{ssub}{\sub@sfcnt\@font@info}

533 \def\sub@sfcnt#1{%
534     \edef\mandatory@arg{\f@encoding/\mandatory@arg}%

```

Next action is split the arg into its individual components and allow for a late font shape load.

```
535     \begingroup
536     \expandafter\split@name\mandatory@arg/\@nil
537     \try@load@fontshape
538     \endgroup

```

Then we record the current `\f@size` since it may get clobbered.

```
539     \let\f@user@size\f@size

```

Then we check whether this new combination is defined and give an error message if not. In this case we also switch to `\error@fontshape`.

```
540     \expandafter
541     \ifx\csname\mandatory@arg\endcsname\relax
542         \errmessage{No\space declaration\space for\space
543             shape\space \mandatory@arg}%
544         \error@fontshape
545     \else

```

Otherwise we warn the user about the substitution taking place.

```
546         #1{Font\space shape\space '\curr@fontshape'\space in\space
547             size\space <\f@size>\space not\space available\MessageBreak
548             Font\space shape\space '\mandatory@arg'\space tried\space
549             instead}%
550         \expandafter\split@name\mandatory@arg/\@nil
551     \fi

```

Then we restart the font specification scan by calling `\get@external@font`.

```
552     \edef\f@size{\f@user@size}%
553     \get@external@font

```

Finally `\do@subst@correction` is called to get the font name right.

```
554     \do@subst@correction
555 }

```

*(End of definition for `\s@fct@sub`.)*

`\@font@aliasinfo` Sometimes a substitution is only done to map a long font name to a standard shape or series, e.g.,

```
DeclareFontShape{T1}{Roboto-LF}{b}{it}{<-> alias * Roboto-LF/bold/it}{}
```

Using the `ssub` function in that case will give a strange (and incorrect) warning. As an alternative we therefore offer the size function `alias`. It will still add some info into the `.log` file, but no longer complains that the font shape is not available. It is implemented by grabbing the default warning text and replacing it with a new one.

```
556 </2ekernel>
557 <*2ekernel | latexrelease>
558 <latexrelease>\IncludeInRelease{2020/02/02}%
559 <latexrelease>{\font@aliasinfo}{alias size function}%
560 \DeclareSizeFunction{alias}{\sub@sfcnt\font@aliasinfo}
561 \def\font@aliasinfo#1{%
562   \font@info{Font\space shape\space '\curr@fontshape'\space
563     aliased\space to\MessageBreak '\mandatory@arg'}%
564 }
565 </2ekernel | latexrelease>
566 <latexrelease>\EndIncludeInRelease
567 <latexrelease>\IncludeInRelease{0000/00/00}%
568 <latexrelease>{\font@aliasinfo}{alias size function}%
569 <latexrelease>\let\s@sfcnt@alias\@undefined
570 <latexrelease>\let\font@aliasinfo\@undefined
571 <latexrelease>
572 <latexrelease>\EndIncludeInRelease
573 <*2ekernel>
```

*(End of definition for \font@aliasinfo.)*

**\s@sfcnt@subf** The `subf` size function allows substitution of another font. The mandatory argument is the external name of the font to be substituted, the optional argument a size scaling factor like in the default size function. The main difference to the default size function is the warning message.

```
574 \DeclareSizeFunction{subf}{\sub@sfcnt\font@warning}
575 \DeclareSizeFunction{ssubf}{\sub@sfcnt\font@info}
576 \def\sub@sfcnt#1{%
577   #1{Font\space shape\space '\curr@fontshape'\space in\space
578     size\space \f@size\space not\space available\MessageBreak
579     external\space font\space '\mandatory@arg'\space used}%
580   \empty@sfcnt#1%
581 }
```

*(End of definition for \s@sfcnt@subf.)*

**\s@sfcnt@fixed** The `fixed` size function is for using a font at a different size than requested. A warning message is printed, and the external font to be used is taken from the mandatory argument. If an optional argument is present it is used as the ‘at’ size for the font. Otherwise the font is loaded at its design size.

```
582 \DeclareSizeFunction{fixed}{\fixed@sfcnt\font@warning}
583 \DeclareSizeFunction{sfixed}{\fixed@sfcnt\font@info}
584 \def\fixed@sfcnt#1{%
585   \ifx\optional@arg\@empty
586     \let\external@font\mandatory@arg
587   \else
588     \edef\external@font{\mandatory@arg\space at\optional@arg pt}%
589   \fi
590 }
```

```

589 \fi
590 #1{External\space font\space '\external@font'\space loaded\space
591     for\space size\MessageBreak
592     <\f@size>}%
593 }
594 </2ekernel>

(End of definition for \s@fct@fixed.)

```

## File 27

# ltfsscmp.dtx

This file contains the implementation of commands giving compatibility with the original ‘NFSS1’ release of the Font Selection Scheme.

**Warning:** The macro documentation is still basically the documentation from the first NFSS release and therefore in some cases probably not completely accurate.

Version 1 of NFSS is obsolete now for about 20 years (and was “current” only for a short intermediate time) so with the 2015 release these internal interface commands are removed from the kernel and made available via `latexrelease` package so that backward compatibility remains ensured for very old documents.

```
1 <*\latexrelease>
2 \IncludeInRelease{2015/01/01}{\new@fontshape}%

# File 28

## ltfssdcl.dtx

This file contains the main implementation of the font selection scheme commands. See other parts of the L<sup>A</sup>T<sub>E</sub>X distribution, or *The L<sup>A</sup>T<sub>E</sub>X Companion* for higher level documentation of these commands.

**Warning:** The macro documentation is still basically the documentation from the first NFSS release and therefore in some cases probably not completely accurate.

## 1 Interface Commands

```

1  <*2kernel>
2  \message{NFSS declarative interface,}

\in@  \@in is a utility macro with two arguments. It determines whether its first argument
\ifin@ occurs in its second and sets the switch \ifin@ accordingly. The first argument may not
        contain braces nor # (more precisely, tokens of category code 1, 2, or 6).

3  \def\in@#1#2%
4  {%
5      \begingroup
6      \def\in@@##1#1{%
7      \toks@\expandafter{\in@@#2{}-{}#1}%
8      \edef\in@@{\the\toks@}%
9      \expandafter\endgroup
10     \ifx\in@@\@empty
11     \in@false
12     \else
13     \in@true
14     \fi
15 }
16 \newif\ifin@

```

(End of definition for \in@ and \ifin@.)

Before the `\begin{document}` command several *<math versions>* and *<math alphabet identifiers>* may be declared. In principle, there should be exactly one family/series/shape combination be declared for each version/alphabet pair. But we want to allow for defaults as well for automagical filling of holes.

While building the tables for math alphabet identifiers and math versions we keep several lists:

- the list of all math versions, `\version@list`, each entry prefixed by the control sequence `\version@elt`, i.e. this list has the following form

$$\begin{aligned} &\backslash\text{version@elt}\langle\text{version}_1\rangle\backslash\text{version@elt}\langle\text{version}_2\rangle\ldots \\ &\hspace{15em}\backslash\text{version@elt}\langle\text{version}_n\rangle \end{aligned}$$

- the list of all math alphabet identifiers. Here every entry has the form:

$$\begin{aligned} &\backslash\text{group@elt}\langle\text{math group number}\rangle \\ &\{\{\langle\text{default family}\rangle\}\{\langle\text{default series}\rangle\}\{\langle\text{default shape}\rangle\}\}. \end{aligned}$$

- Each defined math alphabet identifier holds a list containing information about the *versions* for which it is defined. This list has a more complicated structure: it looks as follows:

```

\set@alpha<the alphabet identifier itself>
\reserved@c<math version><font info>
...
\@nil

```

where *<font info>* is either `\reserved@e` (if the combination is not defined yet) or

```
{\family}{\series}{\shape}}
```

`\version@list` We initialize the version list to be empty.

```

17 \let\version@list=\@empty
18 \@onlypreamble\version@list

```

(End of definition for `\version@list`.)

`\version@elt`

```

19 \let\version@elt\relax
20 \@onlypreamble\version@elt

```

(End of definition for `\version@elt`.)

`\new@mathversion` The macro `\new@mathversion` is called with the version control sequence as its argument.

```
21 %\def\new@mathversion#1{%
```

The first thing this macro does is to check if the version identifier is already present in `\version@list`. We enclose `\version@list` in braces since it might be empty (if no *version* is defined yet). But this means that we need a suitable number of `\expandafter` primitives.

```

22 % \expandafter\in@\expandafter#1\expandafter{\version@list}%
23 % \ifin@

```

If so it prints an error message. The `\next` macro is used to get rid of the four characters `\mv@` that would otherwise appear at the begin of the version name in the error message.

```

24 % \latex@error{Math version
25 % '\expandafter\@gobblefour\string#1'
26 % already defined}\@eha

```

Otherwise we have a new version, and we can proceed with entering it into the tables. We add it to `\version@list`. This is very easy: we define `\version@elt` (which is the delimiter in `\version@list`) to protect itself and the following token from being expanded and simply redefine `\version@list`.

```

27 % \else
28 % \global\expandafter\newcount\csname c@\expandafter
29 % \gobble\string#1\endcsname
30 % \global\csname c@\expandafter
31 % \gobble\string#1\endcsname\@ne
32 % \def\version@elt{\noexpand\version@elt\noexpand}%
33 % \edef\version@list{\version@list\version@elt#1}%

```

Then we prepare to enter the new version into all math alphabet identifier lists. Remember that these lists use `\reserved@c` as delimiter, and that there appears the control sequence `\reserved@e` that must not be expanded. Therefore we take suitable precautions.

```
34 % \def\reserved@c{\noexpand\reserved@c\noexpand}%
35 % \let\reserved@e\relax
```

We will now go through the `\alpha@list` to process every *math alphabet identifier* in turn. Since this list has `\group@elt` as a delimiter we define this control sequence. It has three arguments as every entry consists of three items (as explained above).

```
36 % \def\group@elt##1##2##3{%
```

The first of these arguments is the *math alphabet identifier*. We redefine it by appending the information about the new version at the end of the list contained in it. However, there is one subtlety: the definitions for `\reserved@c` and `\reserved@e` made above prevent the main part of the list from being expanded. But we still have to take care of the header and the trailer. To do this we remove the trailer by means of the macro `\remove@nil` which also protect the header from being expanded. Its definition is given below. Now we can prepare to add the new version.

```
37 % \edef##1{\expandafter\remove@nil##1%
38 % \reserved@c
39 % #1%
40 % \reserved@e
41 % \noexpand\@nil}}%
```

Finally we call `\alpha@list` which will now execute the macro `\group@elt` once for every defined *math alphabet identifier*. And that's all for now.

```
42 % \alpha@list
43 % \fi}
```

*(End of definition for \new@mathversion.)*

`\alpha@list` As we explained above every entry in `\alpha@list` has the form  
`\alpha@elt`  
*alphabet identifier internal group number default font assignments*...  
We initialize it to `\@empty`.

```
44 \let\alpha@list\@empty
45 \@onlypreamble\alpha@list
```

*(End of definition for \alpha@list.)*

`\alpha@elt`

```
46 \let\alpha@elt\relax
47 \@onlypreamble\alpha@elt
```

*(End of definition for \alpha@elt.)*

`\newgroup` Start the group (fam) allocation at 0. (Doesn't belong here.)

```
48 \count18=-1
```

*(End of definition for \newgroup.)*

`\stepcounter`

*(End of definition for \stepcounter.)*

`\select@group` We surround `\select@group` with braces so that functions using it can be used directly after `_` or `^`. However, if we use oldstyle syntax where the math alphabet doesn't have arguments (ie if `\math@bgroup` is not `\bgroup`) we need to get rid of the extra group.

```

`\c@localmathalphabets` To avoid hitting the “no more math fams available” limit of 16, we keep a defined number of math alphabets flexible/local. If we have to allocate any of those we roll back the allocation after the formula has ended, so the next formula can use other alphabets in the slot(s). This makes the processing a bit slower if you are working at the limit, but that is better than dying with “out of memory”.

```

138 \endkernel
139 \latexrelease\IncludeInRelease{2021/11/15}
140 \latexrelease {\document@select@group}{\document@select@group}%
141 \*2ekernel\latexrelease

```

We don’t really undo the declaration on rollback (as that would be hard to maintain), so rolling forward needs to check if the declaration was already made.

```

142 \ifx\c@localmathalphabets\undefined

```

There is no need to have this counter as part of the include checkpoints, given that it makes little sense to alter its settings mid document. All we want is the ability to change it using the `\setcounter` interface.

By default we keep two math fams flexible.

```

143 \newcount\c@localmathalphabets
144 \setcounter{localmathalphabets}{2}
145 \fi

```

*(End of definition for \c@localmathalphabets.)*

`\document@select@group` The `\document@select@group` command is the version of `\select@group` (inside math versions) that is used in the document body to set up math alphabets (if used).

```

146 \def\document@select@group#1#2#3#4{%
147 \ifx\math@bgroup\bgroup\else\relax\expandafter\@firstofone\fi
148 {%
149 \ifmmode

```

We first check if there is still room for allocating another mathgroup. If there is, we check if it can be globally allocated or if we have reached the limit which is given by `\e@mathgroup@top` with `\c@localmathalphabets` subtracted.

```

150 \ifnum\csname c@mv@\math@version\endcsname<\e@mathgroup@top
151 \ifnum \numexpr\e@mathgroup@top-\c@localmathalphabets
152 >\csname c@mv@\math@version\endcsname
153 \else

```

If we are past this point we freeze the current state of the math version so that we can return to it after the formula has ended. Of course, that should be done only once, so we check if `\mv@<version>@frozen` already exists.

```

154 \ifcsname mv@\math@version @frozen\endcsname \else

```

We have to pass the current value of `\math@version` not the macro itself, because some of the processing is delayed to a point where the value may have changed again—not doing this caused a puzzling error in one setup.

```

155 \expandafter\freeze@math@version\expandafter{\math@version}%

```

Extra \expandafter to remove the \expandafter added below

```

175 \else \expandafter\expandafter\expandafter\non@alpherr\fi

```

We surround \select@group with braces so that functions using it can be used directly after `_` or `^`.

If the legacy interface is used, e.g., `\sf -1` the math alphabet #1 does not take an argument so we better do not surround #4 with braces, because then we get `{\relax}` into the formula and introduce an extra Ord atom. The two different cases can be distinguished by looking at the current value of `\math@bgroup`.

```

**\freeze@math@version** This command stores the current state of the math version and sets things up to return to it after each formula from now on. We use L3 programming layer code to set it up.

```

274 </2ekernel>
275 <*2ekernel | latexrelease>
276 <latexrelease> \IncludeInRelease{2022/11/01}%
277 <latexrelease> {\freeze@math@version}{freeze math version}%
278 \ExplSyntaxOn
279 \cs_new_protected:Npn\freeze@math@version #1 {

```

Save the current \mv@<version> code and the number of allocated mathgroups inside.

```

280 \font@info{Freeze~ math~ alphabet~ allocation~ in~ version~
281 #1.\MessageBreak
282 Allocated~math~groups:~\int_use:c{ c@mv@ #1 }~
283 (local:~ \int_use:N\c@localmathalphabets) }
284 \cs_gset_eq:cc { mv@#1@frozen }{ mv@#1 }
285 \tl_gset:cx { g__nfss_frozen_mv_ #1 _tl }{ \int_use:c { c@mv@#1 } }

```

Here is the definition of \mv@<version>@reset. If there has been no new math alphabet allocation, doing a reset would just cause a lot of unnecessary processing, so we do a quick check upfront for this.

```

286 \cs_gset:cpn{mv@#1@reset}
287 {

```

If we are back at top-level, or more precisely outside of any (nested) math, we may have to reset the math version back to its frozen version, if that exists and has fewer alphabets allocated.

```

288 \int_compare:nNnTF \math@level = 0
289 {
290 \int_compare:nNnTF { \int_use:c{c@mv@#1} } >
291 { \tl_use:c{g__nfss_frozen_mv_ #1 _tl} }
292 {
293 \font@info{ Undo~ math~ alphabet~ allocation~ in~ version~ #1 }

```

If the undo is necessary, we restore the \mv@<version> code.

```

294 \cs_gset_eq:cc { mv@#1 }{ mv@#1@frozen }
295 \int_gset:cn { c@mv@#1 }{ \tl_use:c {g__nfss_frozen_mv_ #1 _tl} }

```

But we also should undo changes to the top-level math alphabet definitions. We therefore run this code with a modified definition for `\getanddefine@fonts` because there is no need to do anything to the symbol fonts that are permanently allocated. However, we do this only if the resetting was for the current math version, because otherwise we would give the top-level definitions the values for the last math version being resetted (e.g., bold if there are just two).

```

296         \tl_if_eq:NnTF \math@version {#1}
297         {
298             \group_begin:
299             \cs_set_eq:NN \getanddefine@fonts \use_none:nn
300             \use:c {mv@ \math@version }
301             \group_end:
302         }
303     {

```

Once we have hit the boundary and have to revert to the frozen version that happens quite often, but typically only for the normal version. Thus, it is better to report only when we do not revert the top-level definition as this is the exceptional case and happens only if several math versions are used in parallel.

```

304         \@font@info{ ...~ but~ do~ not~ reset~ the~
305             top-level~ math~ alphabet~ definitions }
306     }
307 }
308 {

```

If there was no change, we report that in the log (but this branch could go completely).

```

309         \@font@info{ No~ math~ alphabet~ change~
310             to~ frozen~ version~ #1 }
311     }
312 }
313 {
314     \@font@info{ Nested~ math:~ keeping~ math~ alphabet~
315         allocation~ in~ version~ #1}
316 }

```

If this is executed after a math display, we may have to arrange for ignoring spaces, because they are now hidden if the tokens from above intervene. This is signaled by the 2e switch `@ignore` which is set in `\frozen@everymath` and `\frozen@everydisplay`.

This is all 2e code so we use that syntax.

**\@xxDeclareMathDelimiter**

This macro checks if the second arg is a “math type” such as `\mathopen`. The undocumented original code didn’t use math types when the delimiter was a single letter. For this reason the coding is a bit strange as it tries to support the undocumented syntax for compatibility reasons.

```

1045 \def\@xxDeclareMathDelimiter#1#2#3#4{%

```

7 is the default value returned in the case that `\mathchar@type` is passed something unexpected, like a math symbol font name. We locally move `\mathalpha` out of the way so if you use that the right branch is taken. This will still fail if an explicit number 7 is used!

```
1046 \begingroup
1047 \let\mathalpha\mathord
1048 \ifnum7=\mathchar@type{#2}%
1049 \endgroup
```

If this branch is taken we have old syntax (5 arguments).

```
1050 \expandafter\@firstofone
1051 \else
```

If this branch is taken `\mathchar@type` is different from 7 so we assume new syntax. In this case we also use the arguments to set up the letter as a math symbol for the case where it is not used as a delimiter.

```
1052 \endgroup
1053 \DeclareMathSymbol#1{#2}{#3}{#4}%
```

Then we arrange that `\@xDeclareMathDelimiter` only gets #1, #3, #4 ... as it does not expect a math type as argument.

```

1238 \fi
1239 \fi
1240 \fi
1241 \fi
1242 \fi
1243 \fi
1244 \fi}
1245 \@onlypreamble\mathchar@type

(End of definition for \mathchar@type.)

\DeclareSymbolFontAlphabet

1246 \def\DeclareSymbolFontAlphabet#1#2{%
1247 \expandafter\DeclareSymbolFontAlphabet@
1248 \csname \expandafter\@gobble\string#1\space\endcsname{#2}#1}
1249 \@onlypreamble\DeclareSymbolFontAlphabet

(End of definition for \DeclareSymbolFontAlphabet.)

\DeclareSymbolFontAlphabet@
1250 \def\DeclareSymbolFontAlphabet@#1#2#3{%
We use the switch \if@tempswa to decide if we can declare this symbol font alphabet.
1251 \@tempwatrue

```

First check if #2 is known to be a symbol font

```
1252 \expandafter\in@\csname sym#2\expandafter\endcsname
1253 \expandafter{\group@list}%
1254 \ifin@
```

Check if #1 is defined as a math alphabet defined via `\DeclareMathAlphabet`:

```
1255 \expandafter\in@\expandafter#1\expandafter{\alpha@list}%
1256 \ifin@
```

If so remove it from the `\alpha@list` and from all math version macros.

```
1257 \@font@info{Redeclaring math alphabet \string#3}%
1258 \toks@{}%
1259 \def\alpha@elt##1##2##3{%
1260 \ifx##1#1\else\addto@hook\toks@{\alpha@elt##1##2##3}\fi}%
1261 \alpha@list
1262 \xdef\alpha@list{\the\toks@}%
```

Now we loop over all versions and remove the math alphabet:

```
1263 \def\version@elt##1{%
1264 \begingroup
1265 \toks@{}%
1266 \def\getanddefine@fonts####1####2{%
1267 \addto@hook\toks@{\getanddefine@fonts####1####2}}%
1268 \def\install@mathalphabet####1####2{%
1269 \ifx####1#1\else
1270 \addto@hook\toks@{\install@mathalphabet
1271 #####1{####2}}\fi}%
1272 ##1%
1273 \xdef##1{\the\toks@}%
1274 \endgroup
1275 }%
1276 \version@list
1277 \else
```

If #3 is not defined as a math alphabet check if it is defined at all:

```
1278 \expandafter\ifx
1279 \csname\expandafter\@gobble\string#1\space\endcsname
1280 \relax
```

If it is undefined, fine otherwise check if it is a math alphabet defined via `\DeclareSymbolFontAlphabet`:

```
1281 \else
1282 \edef\reserved@a{%
1283 \noexpand\in@{\string\use@mathgroup}{\meaning#1}}%
1284 \reserved@a
1285 \ifin@
1286 \@font@info{Redeclaring math alphabet \string#3}%
1287 \else
```

Since the command #3 is defined to be something which is not a math alphabet we have to skip redefining it.

```
1288 \@tempswafalse
1289 \@latex@error{Command ‘\string#3’ already defined}\@eha
1290 \fi
1291 \fi
1292 \fi
1293 \else
```

Since the symbol font is not known we better skip defining this alphabet.

```

1294     \@tempswafalse
1295     \@latex@error{Unknown symbol font '#2'}\@eha
1296     \fi
1297     \if@tempswa

```

When we reach this point we are allowed to define #1 to be a symbol font math alphabet. This means that we have to set it to

```
\use@mathgroup <math-settings> \sym<name>
```

The `<math-settings>` are the one for the encoding that is used in the font shape where `\sym<name>` is pointing to. This means that we have to get it from the information stored in `\group@list`. Thus we loop through that list after defining `\group@elt` in a suitable way.

```

1298     \def\group@elt##1##2{%
1299         \expandafter\ifx\csname sym#2\endcsname##1%
1300         \expandafter\reserved@a\string##2\@nil
1301         \fi}%
1302     \def\reserved@a###2/##3\@nil{%
1303         \def\reserved@a{##2}}%
1304     \group@list
1305     \toks@{\relax\ifmmode \else \non@alpherr#1\fi}%
1306     \edef#1{\the\toks@
1307         \noexpand\use@mathgroup
1308         \expandafter\noexpand\csname M@\reserved@a\endcsname
1309         \csname sym#2\endcsname}%
1310     \def#3{\protect#1}%
1311     \fi
1312 }
1313 \@onlypreamble\DeclareSymbolFontAlphabet@
1314 </2ekernel>

```

(End of definition for \DeclareSymbolFontAlphabet@.)

## File 29

# ltfssini.dtx

This file contains the top level L<sup>A</sup>T<sub>E</sub>X interface to the font selection scheme commands. See other parts of the L<sup>A</sup>T<sub>E</sub>X distribution, or *The L<sup>A</sup>T<sub>E</sub>X Companion* for higher level documentation of these commands.

## 1 NFSS Initialization

Finally, there are six commands that are to be used in L<sup>A</sup>T<sub>E</sub>X and that we will therefore protect against expansion at the wrong point: `\fontfamily`, `\fontseries`, `\fontshape`, `\fontsize`, `\selectfont`, and `\mathversion`.

```
1 <*2kernel>
2 \message{NFSS initialization,}
```

### 1.1 Providing math *versions*

L<sup>A</sup>T<sub>E</sub>X provides two *versions*. We call them normal and bold, respectively.

```
3 \DeclareMathVersion{normal}
4 \DeclareMathVersion{bold}
```

Now we define the standard font change commands. We don't allow the use of `\rmfamily` etc. in math mode.

(Actually most are now defined further down in the file.)

First the changes to another *family*:

```
5 %\DeclareRobustCommand\rmfamily
6 %      {\not@math@alphabet\rmfamily\mathrm}
7 %      \fontfamily\rmdefault\selectfont}
8 %\DeclareRobustCommand\ssfamilly
9 %      {\not@math@alphabet\ssfamilly\mathsf}
10 %      \fontfamily\sfdefault\selectfont}
11 %\DeclareRobustCommand\ttfamily
12 %      {\not@math@alphabet\ttfamily\mathtt}
13 %      \fontfamily\ttdefault\selectfont}
```

Then the commands changing the *series*:

```
14 %\DeclareRobustCommand\bfseries
15 %      {\not@math@alphabet\bfseries\mathbf}
16 %      \fontseries\bfdefault\selectfont}
17 %\DeclareRobustCommand\mdseries
18 %      {\not@math@alphabet\mdseries\relax}
19 %      \fontseries\mddefault\selectfont}
20 \DeclareRobustCommand\upshape
21      {\not@math@alphabet\upshape\relax}
22      \fontshape\updefault\selectfont}
```

Then the commands changing the *shape*:

```
23 \DeclareRobustCommand\slshape
24      {\not@math@alphabet\slshape\relax}
25      \fontshape\sldefault\selectfont}
26 \DeclareRobustCommand\scshape
```

```

27         {\not@math@alphabet\scshape\relax
28          \fontshape\scdefault\selectfont}
29 \DeclareRobustCommand\itshape
30     {\not@math@alphabet\itshape\mathit
31      \fontshape\itdefault\selectfont}

```

## 2 Custom series settings for main document families

This section was introduced 2020/02/02 and for now we support a full rollback (may need splitting later).

```

32 </2ekernel>
33 <*2ekernel | latexrelease>
34 <latexrelease>\IncludeInRelease{2021/11/15}%
35 <latexrelease>          {\DeclareFontSeriesDefault}{Custom series}%

```

One problem with the NFSS approach of handling the series axis turned out to be that (especially with respect to “boldness”) different font families implemented different strategies. For example, with Computer Modern fonts you normally only have **bx** whereas most PostScript fonts offered only **b** but not **bx**. As a result L<sup>A</sup>T<sub>E</sub>X’s standard setting for `\bfdefault` didn’t work with such fonts, but if it got changed to produce **b**, then that didn’t work with Computer Modern if the fonts got combined (e.g., using Computer Modern Typewriter with such fonts).

The solution back then was to provide substitution rules in the font `.fd` such that if a **bx** series got requested the **b** series got used. While this works in that particular case, it isn’t a very general solution. For example, if you happen to have a font family that has several weights you may want to typeset the whole document in a somewhat lighter or darker font but if you then modify `\mddefault` to allow for this, then of course your change only works with that particular family but not with the typewriter or sans serif family you also want to use.

A better solution was provided by the `mweights` package by Bob Tennent that offers defaults on the level of the three main font families in the document: for “rm”, “sf” and “tt” so that font packages could define defaults for the sans serif document font by providing `\bfseries@sf` which then was used when `\bfseries` got executed and the current family was the `\sffamily`.

`\DeclareFontSeriesDefault` We now support this concept directly from within L<sup>A</sup>T<sub>E</sub>X and for use in font packages (or the document preamble) we offer `\DeclareFontSeriesDefault`. This declaration takes three arguments:

**document family interface:** Can either be `rm`, `sf` or `tt`. This is optional and if not given the overall default.

**document series interface:** Can be `md` or `bf`.

**series value:** This is the value that is going to be used with the combination is requested.

For example, `\DeclareFontSeriesDefault[rm]{bf}{sb}` would use **sb** (semi-bold) when `\rmfamily \bfseries` is asked for.

If used without the optional argument, e.g., `\DeclareFontSeriesDefault{bf}{b}` then this is like redefining `\bfdefault` or `\mddefault`.

If some family specific defaults aren't given, e.g. if there are no declarations for, say, `tt` then the format defaults of `\mddefault` and `\bfdefault` are assumed. If those are later changed this is *not* reflected!<sup>37</sup>

`\DeclareFontSeriesDefault` The command to declare font series defaults for the “rm”, “sf” or “tt” family.

```

36 \let\DeclareFontSeriesDefault\undefined      % for rollback
37 \newcommand\DeclareFontSeriesDefault[3][]{%

38   \expand@font@defaults
39   \maybe@update@bfseries@defaults
40   \maybe@update@mdseries@defaults

41   \def\reserved@a{#1}%

```

No optional argument: set up general default.

```

42   \ifx\reserved@a\@empty
43     \ifcsname #2series\endcsname              % supported are
44                                           % \[md/bf]default

```

Adding `\@empty` allows us to detect if the default gets redefined with `\renewcommand` or `\def` by the user.

```

45     \expandafter\def
46       \csname #2default\endcsname{#3\@empty}%
47     \expandafter\def
48       \csname #2default@previous\endcsname{#3\@empty}%
49   \else

50     \@latex@error{Wrong syntax for \string\DeclareFontSeriesDefault}%
51     {Mandatory first argument must be 'md' or 'bf'.}
52   \fi

```

Optional argument given, set up specific default.

```

53   \else
54     \ifcsname #2series@#1\endcsname          % supported are
55                                           % \[md/bf]series@[rm/sf/tt]

56     \expandafter\edef
57       \csname #2series@#1\endcsname{#3}%

```

If the interface is used we remove the frozen kernel default. This way, we know that something was explicitly set up (even if the setup has the same value as the default).

```

58     \expandafter\let
59       \csname #2series@#1@kernel\endcsname\@undefined
60   \else
61     \@latex@error{Wrong syntax for \string\DeclareFontSeriesDefault}%
62     {Optional argument must be 'rm', 'sf', or 'tt'. \MessageBreak
63       Mandatory first argument must be 'md' or 'bf'.}
64   \fi
65 \fi
66 }

```

---

<sup>37</sup>I see no easy way to achieve this without compromising compatibility with existing packages that currently use `mweights` and directly define (some) of the `\mdseries@...` commands but not others.

(End of definition for \DeclareFontSeriesDefault.)

128 <latexrelease> \mdseries@rm}{Custom series}%

`\mdseries@rm` We initialize the family specific default at the end of the format generation. Later on  
`\mdseries@sf` they may get overwritten in the preamble or a package via `\DeclareFontSeriesDefault`  
`\mdseries@tt` (or possibly directly).

`\bfseries@rm` Conceptual change: The `\bfdefault` will be `b` not `bx` because that is what it should  
`\bfseries@sf` be really for nearly every font except Computer/Latin Modern.

`\bfseries@tt` To account for the fact that by default we typeset in CM or LM we set up the  
`\bfseries@..` defaults to use `bx` instead.

This means that it behaves like before because if the default fonts are used then  
`\bfseries@rm` etc kick in and make `\textbf` use `bx`. However, if the font gets changed  
then `\bfdefault` will get used.

129 \def\bfseries@rm{bx}

130 \def\bfseries@sf{bx}

131 \def\bfseries@tt{bx}

Frozen version of the kernel defaults so we can see if they have changed.

132 \let\bfseries@rm@kernel\bfseries@rm

133 \let\bfseries@sf@kernel\bfseries@sf

134 \let\bfseries@tt@kernel\bfseries@tt

The default for the medium series is `m` and this will be interpreted as resetting both  
weight and width. To reset only one of them the virtual value `?m` and `m?` are available.

135 \def\mdseries@rm{m}

136 \def\mdseries@sf{m}

137 \def\mdseries@tt{m}

(End of definition for `\mdseries@rm` and others.)

`\series@change@debug` For debugging, but right now none of this code is extracted. The idea is to have a separate  
package with debugging code one day.

138 <\*debug>

159 <*2ekernel | latexrelease>
160 <latexrelease>\IncludeInRelease{2025/11/01}%
161 <latexrelease>    {\prepare@family@series@update}{Support meta family}%

```

`\prepare@family@series@update` This is core command that prepares for the family update. The big difference to the documented code above is that the nested `\ifx` statements seem to be missing. Instead we loop through an internal list that holds the names of the three meta families. This approach allows us to extend the mechanism at a later stage to allow for additional named meta families.

Here is the current definition of that list:

```

\@meta@family@list 162 \def\@meta@family@list{\@elt{rm}\@elt{sf}\@elt{tt}}

```

This macro holds the current “meta” family. At the moment it is either `rm`, `sf`, `tt` or `??`.

`\@currentmetafamily` The latter is used if the current font family does not match any of the document meta families, defined through `\rmdefault`, `\sfdefault` or `\ttdefault`, i.e., in the case that yet another family was selected using `\fontfamily` manually.

The value gets updated by commands like `\rmfamily`, etc.

```

163 \def\@currentmetafamily{??}

164 \def\prepare@family@series@update#1#2{%

```

We start by updating the meta family.

```

165 \def\@currentmetafamily{#1}%

166 \if@forced@series
167 <+debug> \series@change@debug{No series preparation (forced \f@series)\on@line}%
168 \fontfamily#2%
169 \else
170 <+debug> \series@change@debug{Preparing for switching to #1 (#2)\on@line}%
171 \expand@font@defaults

```

We prepare for changing the current series. We have to find it before changing the family as discussed above.

```

172 \let\target@series@value\@empty

```

As the very last item in the meta family list we add `\@elt{??}` and define this pseudo meta family to be the current font family. So if none of the real meta families matched then this will match. This will cover the following case:

- `\bfseries` is called for a family using `bx` (e.g., `CMR`)
- Switch to a font family that is none of the meta families, e.g., via `\fontfamily{ptm}\allowbreak\`

- Then none of the real meta families, match but the final `\@elt{??}` will.
- Therefore if the current series is `\mddefault` or `\bfdefault` it will be detected and the corresponding target series selected.

```
173 \expandafter\edef\csname ??def@ult\endcsname{\f@family}%
```

To find it we loop over the meta family list with a suitable definition of `\@elt`.

```
174 \let\@elt\update@series@target@value
175 \@meta@family@list
```

Last resort pseudo meta family. Will only be looked at if none of the real ones have matched.

```
176 \@elt{??}%
177 \let\@elt\relax
```

That will figure out the correct series value to use without updating it. Now we can change the family.

```
178 \fontfamily#2%
```

After that we update the series. That code is again like the one above.

```
179 \ifx\target@series@value\@empty
180 <+debug> \series@change@debug{Target series still empty ...}%
181 \else
182 \ifx \f@series\target@series@value
183 <+debug> \series@change@debug{Target series unchanged:
184 <+debug> \f@series \space = \target@series@value}%
185 \else
186 \maybe@load@fontshape
187 <+debug> \series@change@debug{Target series:
188 <+debug> \f@series \space -> \target@series@value}%
```

The `\target@series@value` may contain something like `cm` (coming from a default) and so we can't directly assign it to `\f@series` we have to drop any surplus `m` first.

```
189 % \let\f@series\target@series@value
190 \series@maybe@drop@one@m\target@series@value\f@series
191 \fi
192 \fi
193 \fi
194 }
```

(End of definition for `\prepare@family@series@update`, `\@meta@family@list`, and `\@currentmetafamily`.)

`\update@series@target@value` In this macro you basically find the nested `\ifxs` from the outline above. The only difference is that it is parameterized instead of being written out. And we have only for one block of tests because the code is called repeatedly when looping over the meta family list. From the `\@meta@family@list` list we get each meta family name in turn.

```
195 \def\update@series@target@value#1{%
```

There is one additional test at the beginning, because the list contains all meta families and we need to ignore the case where current one from the list and target one are identical.

```
196 \def\reserved@a{#1}%
197 \ifx\@currentmetafamily\reserved@a % rm -> rm do nothing
198 \else
```

```

199 <+debug> \series@change@debug{Trying to match #1: \csname#1def@ult\endcsname
200 <+debug> \space = \f@family\space ?}%

```

We only “do” something if the current font family matches the current meta family.

```

201 \expandafter\ifx\csname#1def@ult\endcsname\f@family

```

If that’s the case we know that this is the block that applies (only one meta family can match). So to speed things up we change `\@elt` so that the rest of the loop gets gobbled.

```

202 \let\@elt\@gobble

```

Then we try to find the right new value for the series (as explained above). The two macros defined first are only there because we now need to use `\csname` and this way the code will be a little faster.

```

203 \expandafter\let\expandafter\reserved@b
204 \csname mdseries@\@currentmetafamily\endcsname
205 \expandafter\let\expandafter\reserved@c
206 \csname bfseries@\@currentmetafamily\endcsname
207 <+debug>\series@change@debug{Targets for mdseries and bfseries:
208 <+debug> \reserved@b\space and \reserved@c}%

```

This here is now identical to the nested `\ifx` block from the outline, except that it there appeared twice in `\rmfamily`. This is now covered by looping and stopping the loop when a match was found.

We have to sanitize the default value first because it may contain something like `mc` and that would never match `\f@series` because there it would be called `c` with the `m` dropped. It would be probably better to do that differently these days, but it is hard to adjust without causing a lot of issues, so we do the dropping in various places instead.

```

209 \expandafter\series@maybe@drop@one@m
210 \csname mdseries@#1\endcsname\reserved@d
211 \ifx\reserved@d\f@series
212 <+debug> \series@change@debug{mdseries@#1 matched -> \reserved@b}%
213 \let\target@series@value\reserved@b
214 \else

```

Again do some sanitizing.

```

215 \expandafter\series@maybe@drop@one@m
216 \csname bfseries@#1\endcsname\reserved@d
217 \ifx\reserved@d\f@series
218 <+debug> \series@change@debug{bfseries@#1 matched -> \reserved@c}%
219 \let\target@series@value\reserved@c
220 \else\ifx\f@series\mddef@ult \let\target@series@value\reserved@b
221 <+debug> \series@change@debug{mddef@ult matched -> \reserved@b}%
222 \else\ifx\f@series\bfdef@ult \let\target@series@value\reserved@c
223 <+debug> \series@change@debug{bfdef@ult matched -> \reserved@c}%
224 \fi\fi\fi\fi
225 \fi
226 \fi
227 }

```

(End of definition for `\update@series@target@value`.)

**`\@restoremetafamily`** In some situations it might be necessary to rerun the command that sets the current meta family, e.g., rerun `\rmfamily` if `rm` is the current meta family (for example, if the hook `rmfamily` contains some conditional code and the condition has changed at that point). The command `\@restoremetafamily` offers a simply way to do this.

```

228 \def\@restoremetafamily{%
229   \csname \@currentmetafamily family\endcsname
230 }

```

This is code to be run at begin document ...

```

299 \def\init@series@setup{%

```

We only want `bx` in `\bfseries@rm` if the roman font is Computer Modern or Latin Modern, otherwise it should be `b`. It was set to `bx` in the kernel so that any font use with the default families in the preamble get this value. Now at the real document start we check if the fonts have been changed. If there was a `\DeclareFontSeriesDefault` declaration or `\bfseries@rm` was directly altered then it differs from `\bfseries@rm@kernel` and we do nothing. Otherwise we check if `\rmdefault` is one of the CM/LM font families and if so we keep `bx` otherwise we change it to `b`.

This approach doesn't cover one case: CM/LM got changed to a different family that supports `bx`, but the support package for that family used `\def\bfseries@rm{bx}` instead of using `\DeclareFontSeriesDefault`. In that case the code here changes it to `b`. Solution: use the `\DeclareFontSeriesDefault` interface.

```

300 \ifx\bfseries@rm@kernel\bfseries@rm
301 \expandafter\in@\expandafter{\rmdefault}%
302 {cmr,cmss,cmtt,lcms,lcmtt,lmr,lmss,lmtt}%
303 \ifin@ \else \def\bfseries@rm{b}\fi\fi

```

Same approach for `\bfseries@sf` and `\bfseries@tt`:

```

304 \ifx\bfseries@sf@kernel\bfseries@sf
305 \expandafter\in@\expandafter{\sfdefault}%
306 {cmr,cmss,cmtt,lcms,lcmtt,lmr,lmss,lmtt}%
307 \ifin@ \else \def\bfseries@sf{b}\fi\fi
308 \ifx\bfseries@tt@kernel\bfseries@tt
309 \expandafter\in@\expandafter{\ttdefault}%
310 {cmr,cmss,cmtt,lcms,lcmtt,lmr,lmss,lmtt}%
311 \ifin@ \else \def\bfseries@tt{b}\fi\fi

```

If the document preamble has changed the `\familydefault` or if the if the `\rmdefault` contains a new font family, we may have to adjust the series defaults accordingly, before starting typesetting.

Similarly, if the user has changed the `\mddefault` or the medium series for the family selected as document font we may also have to adjust the `\seriesdefault`.

On the other hand if the document font is still CM or LM then `\bfdefault` is wrong, because it is now saying `b` and not `bx` as it should for such fonts.

To fix all this we first run `\reset@font` (the internal kernel name for `\normalfont`). This will set up the document encoding, family, series and shape based on the current values of `\encodingdefault`, `\familydefault`, `\seriesdefault` and `\shapedefault`. However, if the family (from `\familydefault`) has special medium default we should switch to that (and not use what is current value from `\seriesdefault`). This can be achieved by afterwards calling `\mediumseries` and then changing `\seriesdefault` to the now current series value (in `\f@series`).

But what should happen if `\seriesdefault` got explicitly changed? In that case the explicit change should survive and we should not alter `\seriesdefault`. This is solved by comparing the current value of `\seriesdefault` with a kernel version saved in the format and if they differ we do not call `\mdseries` or change `\seriesdefault`.

```

312 \reset@font
313 \ifx\seriesdefault\seriesdefault@kernel
314 \mdseries
315 \let\seriesdefault\f@series
316 \fi
317 }%
```

(End of definition for `\init@series@setup`.)

As the kernel code now implements the same functionality as `mweights`, albeit internally coded slightly differently, that package shouldn't be loaded any more. We therefore pretend that it already got loaded. Thus, a font package that tries to load it and then sets `\mdseries@.`, etc. will continue to work but will now use the kernel code.

Of course, mid-term such package should probably use `\DeclareFontSeriesDefault` instead of making using low-level definitions.

```

318 \expandafter\let\csname ver@mweights.sty\endcsname\fmtversion
319 </2ekernel | latexrelease>

332 <latexrelease> \bfseries}{Custom series with hooks}%
```

`\bfseries` This document command switches to the bold series.

```

333 \DeclareRobustCommand\bfseries{%
334 \not@math@alphabet\bfseries\mathbf
```

In the original NFSS definition it then called `\fontseries` with the value `\bfdefault`. In the new scheme we have more alternatives and therefore check if the current family (`\f@family`) is the current `\rmdef@ult`, `\sfdef@ult` or `\ttdef@ult` and then select the correct family default in that case.

```

335 \expand@font@defaults
336 \maybe@update@bfseries@defaults

337 \ifx\f@family\rmdef@ult \fontseries\bfseries@rm
338 \else\ifx\f@family\sfdef@ult \fontseries\bfseries@sf
339 \else\ifx\f@family\ttdef@ult \fontseries\bfseries@tt

```

If not `\bfdefault` is used.

```

340 \else \fontseries\bfdefault
341 \fi\fi\fi

```

This hook in contrast is always executed.

```

342 \UseHook{bfseries}%
343 \selectfont
344 }

```

*(End of definition for \bfseries.)*

`\maybe@update@bfseries@defaults` If `\bfdefault` and `\bfdefault@previous` are different then the default got changed directly through the legacy interface (i.e., via `\def` or `\renewcommand`). In that case we reset all meta family defaults so that the document behaves like it was the case before the new mechanism was introduced.

```

345 \def\maybe@update@bfseries@defaults{%
346 \ifx\bfdefault\bfdefault@previous\else

```

We add `\@empty` and then let `\bfdefault@previous` to `\bfdefault` so that we can detect any further change.

```

347 \expandafter\def\expandafter\bfdefault
348 \expandafter{\bfdefault\@empty}%
349 \let\bfdefault@previous\bfdefault

```

And we reset the meta family defaults (`\bfdef@ult` is an expanded version of `\bfdefault`).

```

```

`\expand@font@defaults` The family specific defaults are fully expanded, i.e., they are defined via `\edef` inside `\rm@def@ult` `\DeclareFontSeriesDefault`. However, the overall defaults, e.g., `\bfdefault` may have been redefined by the user and thus may not be fully expanded. So to enable reliable comparison we make expanded versions of them. That we rerun each time. The alternative would be to only allow for changes before begin document.

```

\sf@def@ult
\tt@def@ult
\md@def@ult
\bf@def@ult
476 \def\expand@font@defaults{%
477   \edef\rmdef@ult{\rmdefault}%
478   \edef\sfdef@ult{\sfdefault}%
479   \edef\ttdef@ult{\ttdefault}%

```

The series defaults may contain some surplus `m` that we need to drop here.

```

480   \series@maybe@drop@one@m\bfdefault\bfdef@ult
481   \series@maybe@drop@one@m\mddefault\mddef@ult

```

Formats that set up parallel fonts, e.g., for Japanese, can use this hook to add additional code here.

```

482   \UseHook{expand@font@defaults}%
483 }

```

(End of definition for `\expand@font@defaults` and others.)

`\rmfamily` Here are the document level commands for changing the main font families, or rather, here is a documented outline of the code, the actual code is then streamlined and somewhat generalized.

```

DeclareRobustCommand\rmfamily{%
  \not@math@alphabet\rmfamily\mathrm

```

If families are changed then we have to do a bit more work. In the original NFSS implementation a family change kept encoding, series shape and size unchanged but now we can't any longer simply reuse the current series value. Instead we may have to change it from one family default to the next.

```

\expand@font@defaults

```

We have to do the testing while the current family is still unchanged but we have to do the adjustment of the series after it got changed (because the new family might have different sets of shapes available and we certainly don't want to see substitution going on. So we use `\target@series@value` to hold the target series (if any).

```

\let\target@series@value\@empty

```

Thus, if the current family is the sans family

```
\ifx\f@family\sfdef@ult
```

and if we using the medium series of the sans family

```
\ifx\f@series\mdseries@sf
```

then lets switch to the medium series for the serif family

```
\let\target@series@value\mdseries@rm
```

and if we use the bold series of the sans family switch to the bold default of the serif family:

```
\else\ifx\f@series\bfseries@sf \let\target@series@value\bfseries@rm
```

However, the sans family may not have any specific defaults set, so we also compare with the overall defaults.

```
\else\ifx\f@series\mddef@ult \let\target@series@value\mdseries@rm  
\else\ifx\f@series\bfdef@ult \let\target@series@value\bfseries@rm
```

If neither test was true we leave the series alone. This way a special manual setting such as `\fontseries{lc}` is not undone if the family changes (of course there may not be any support for it in the new family but then the NFSS substitution kicks in and sorts it out).

```
\fi\fi\fi\fi
```

We need to do the same if the current family is the typewriter family:

```
\else\ifx\f@family\ttdef@ult  
  \ifx\f@series\mdseries@tt \let\target@series@value\mdseries@rm  
  \else\ifx\f@series\bfseries@tt \let\target@series@value\bfseries@rm  
  \else\ifx\f@series\mddef@ult \let\target@series@value\mdseries@rm  
  \else\ifx\f@series\bfdef@ult \let\target@series@value\bfseries@rm  
  \fi\fi\fi\fi  
\fi\fi
```

With these preparations for series out of the way we can now change the font family to `\rmdefault`.

```
\fontfamily\rmdefault
```

If `\target@series@value` is still empty there is nothing more to do other than selecting the new family. However, if not then we should update the font series now as well. But there is one further subtle issue. We may not have loaded an `.fd` file for our target font family yet. In the past that was done in `\selectfont` if necessary but since we are now doing all the comparisons in `\fontseries` we need to make sure that the font family specifications are already loaded prior to calling `\fontseries`.

```
\ifx\target@series@value\@empty \else  
  \maybe@load@fontshape
```

Updating the series in this case means directly changing `\f@series` to the target value. We don't want to go through `\fontseries` because that would apply the mappings and then `bx + b` would keep `bx` instead of changing to `b` as desired. as

```
\let\f@series\target@series@value
\fi
\selectfont}
```

So now for the real definition: most of the code above gets delegated to a helper command `\prepare@family@series@update` so that the definition becomes again fairly short. In addition we add a hook, mainly for our Japanese friends so that the code can be extended prior to the call to `\selectfont`.

```
484 \DeclareRobustCommand\rmfamily{%
485   \not@math@alphabet\rmfamily\mathrm
```

This holds all the code discussed above, first argument is the meta family, i.e., `rm` in this case, and second argument is the default family name, e.g., `cmr` indirectly accessed via `\rmdefault`. This is calling `\fontfamily` and if necessary `\fontseries` as outline above.

```
486   \prepare@family@series@update{rm}\rmdefault
```

Then comes the hook code (by default a no-op) and finally the call to `\selectfont`.

```
487   \UseHook{rmfamily}%
488   \selectfont}
```

The definitions for `\sffamily` and `\ttfamily` are similar, the differences are only in what font families get checked.

```
\sffamily
\ttfamily
489 \DeclareRobustCommand\sffamily{%
490   \not@math@alphabet\sffamily\mathsf
491   \prepare@family@series@update{sf}\sfdefault
492   \UseHook{sffamily}%
493   \selectfont}

494 \DeclareRobustCommand\ttfamily{%
495   \not@math@alphabet\ttfamily\mathtt
496   \prepare@family@series@update{tt}\ttdefault
497   \UseHook{ttfamily}%
498   \selectfont}
```

*(End of definition for \rmfamily, \sffamily, and \ttfamily.)*

```
rmfamily  Declare the hooks used above.
sffamily  499 \NewHook{rmfamily}
ttfamily  500 \NewHook{sffamily}
normalfont 501 \NewHook{ttfamily}
expand@font@defaults 502 \NewHook{normalfont}
bfseries  503 \NewHook{expand@font@defaults}
bfseries/defaults 504 \NewHook{bfseries}
mdseries  505 \NewHook{bfseries/defaults}
mdseries/defaults 506 \NewHook{mdseries}
507 \NewHook{mdseries/defaults}
```

*(End of definition for rmfamily and others.)*

```

\@rmfamilyhook These four hooks have legacy versions used in 2020/02/02 so we should support them
\@sffamilyhook until they aren't any longer used.
\@ttfamilyhook By default the hooks do nothing and in new code they should not any longer be
\@defaultfamilyhook used. Instead use the standard hook system and the hook names rmfamily, sffamily,
                    ttfamily. Instead of \@defaultfamilyhook use normalfont.

508 \let\@rmfamilyhook\@empty
509 \let\@sffamilyhook\@empty
510 \let\@ttfamilyhook\@empty
511 \let\@defaultfamilyhook\@empty

(End of definition for \@rmfamilyhook and others.)

```

`\IfFontSeriesContextTF` With the ability for `\bfseries` or `\mdseries` to be mapped to different NFSS axis values it becomes important to have the ability to determine the current context as we can no longer look at `\fontseries` to answer a question such as “am I currently typesetting in a bold typeface?”

This is provided by the test `\IfFontSeriesContextTF`. It takes three arguments:

- The context we try to check (either `bf` for bold or `md` for medium, i.e., the same that can go into the first mandatory argument of `\DeclareFontSeriesDefault`),
- what to do if we are in this context (true case) and
- what to do if we are not (false case).

This allows you to define commands like `\IfBold`, e.g.,

```
\NewDocumentCommand\IfBold{mm}{\IfFontSeriesContextTF{bf}{#1}{#2}}
```

and then do

```
This is \IfBold{bold}{non-bold} text.
```

and get the appropriate result.

```

575 </2ekernel>
576 <*2ekernel | latexrelease>
577 <latexrelease>\IncludeInRelease{2020/10/01}%
578 <latexrelease>          {\IfFontSeriesContextTF}{Font series context}%
579 \DeclareRobustCommand\IfFontSeriesContextTF[1]{%
580   \expand@font@defaults

```

In the beginning we haven’t found the context we are looking for.

```
581   \@font@series@contextfalse
```

We store the requested context away for use in the tests.

```
582   \def\requested@test@context{#1}%
```

The next definition is there to ensure that get a final match during testing even if the current family is non of the meta families (`rm`, `sf` or `tt`). This will then basically tests if the current font family matches the overall default.

```
583 \expandafter\edef\csname ??def@ult\endcsname{\f@family}%
```

Then we run through the meta family list (currently containing just the three values) followed by the artificial meta family `??` and test each of them in turn using `\test@font@series@context` as the testing command.

```
584 \let\@elt\test@font@series@context
585 \@meta@family@list
586 \@elt{??}%
587 \let\@elt\relax
```

Following that we evaluate the status of `\if@font@series@context` to determine which of the remaining arguments (true/false case) we have to execute.

```
588 \if@font@series@context
589 \expandafter\@firstoftwo
590 \else
591 \expandafter\@secondoftwo
592 \fi
593 }
```

The T/F variants were introduced in 2025 but to simplify rollback we pretend that this happened at the same time as `\IfFontSeriesContextTF`.

```
594 \long\def\IfFontSeriesContextT#1{\IfFontSeriesContextTF{#1}{}}
595 \def\IfFontSeriesContextF{\IfFontSeriesContextTF{}}
```

*(End of definition for \IfFontSeriesContextTF.)*

`\test@font@series@context` This tests the context (stored in `\requested@test@context`) and updates the boolean if the right context is found.

```
596 \def\test@font@series@context#1{%
```

First task is to figure out whether the current family matches `\rmfamily`, `\sffamily`, etc. so in `\reserved@a` we store the value of `\rmdef@ult` (or whatever the given meta family is) and compare that to `\f@family`.

```
597 \edef\reserved@a{\csname #1def@ult\endcsname}%
598 \ifx\f@family\reserved@a
```

If they match we have found the right meta family so we don't need to test any of the remaining meta family and therefore change `\@elt` to `\@gobble`.

```
599 \let\@elt\@gobble
```

Now we have to test if `\f@series` matches the requested context (e.g., whether `\bfseries@rm` has that value if the current meta family is `rm` and we are looking for the `bf` context).

```
600 \expandafter\ifx
601 \csname\requested@test@context series@#1\endcsname\f@series
```

If yes we change the boolean and are done.

```
602 \@font@series@contexttrue
```

If not then maybe the reason is that nothing special was set up for that meta family so we also check now check if `\f@series` matches the overall default (e.g., `\bfdef@ult` if we are looking for the bold context). If that matches we change the boolean.

```

603     \else
604         \expandafter\ifx
605             \csname\requested@test@context def@ult\endcsname\f@series
606             \@font@series@contexttrue
607     \fi\fi\fi
608 }

```

(End of definition for `\test@font@series@context`.)

`\if@font@series@context` The boolean to signal if we found the requested font series context.

```

609 \newif\if@font@series@context
610
611 (End of definition for \if@font@series@context.)
612
613 </2ekernel | latexrelease>
614 <latexrelease>\EndIncludeInRelease

```

### 3 Supporting nested emphasis

By default L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> supports two levels of nested emphasis: if the current font has an upright shape then it switches to `\itshape` otherwise to `\emminnershape` (which defaults to `\upshape`). This means nested emphasis will oscillate between italic and upright shapes.

Sometimes it would be nice to allow for a more lengthy sequence, but instead of providing a fixed one L<sup>A</sup>T<sub>E</sub>X now offers a general mechanism that allows to define arbitrary sequences.

`\DeclareEmphSequence`

`\emforce`

This declaration expects a comma separated list of (font) change declarations corresponding to increasing levels of emphasis. The mechanism tries to be “smart” and verifies that the declarations actually alter the font. If not it will ignore this level and tries the next one—the assumption being that there was a manual font change in the document to the font that is now supposed to be used for emphasis. Of course, this only works if the declarations in the list actually change the font and not, say, just the color. In such a case one has to use `\emforce` to which directs the mechanism to use the level even if the font attributes haven’t changed.

`\emreset`

If the nesting is so deep, that the specified levels are exhausted then `\emreset` is used as a final set of declarations (which by default returns back to the upright shape). Any additional nesting levels will then reuse the list from its beginning.

`\DeclareEmphSequence` `\DeclareEmphSequence` expects a clist of declaration. Spaces in the argument are dropped to avoid spurious spaces in the output. The declarations are additive. At the very end the shape is reset using `\emreset` and `\emforce` so that this case is never skipped.<sup>38</sup> Further nested calls restart at the beginning.

```

624 </2ekernel>
625 <*2ekernel|latexrelease>
626 <latexrelease>\IncludeInRelease{2020/02/02}%
627 <latexrelease>{\DeclareEmphSequence}{Nested emph}%
628 \def\DeclareEmphSequence#1{%
629   \protected@edef\emfontdeclare@clist{\zap@space#1, \@empty\emforce\emreset}%
630 }

```

By default the it is empty, in which case `\eminnershape` is used by L<sup>A</sup>T<sub>E</sub>X.

```

631 \let\emfontdeclare@clist\@empty

```

*(End of definition for \DeclareEmphSequence.)*

`\emrest` Reset the font to upright and upper/lower case. With the default rules using `\shapedefault` does that for us but to be on the safe side we do it like this:

```

632 \DeclareRobustCommand\emreset{\upshape\ulcshape}

```

*(End of definition for \emrest.)*

`\em` The new definition for `\em` (and implicitly `\emph`) is the same as before as long as `\emfontdeclare@clist` is empty.

```

633 \DeclareRobustCommand\em{%
634   \@nomath\em
635   \ifx\emfontdeclare@clist\@empty
636     \ifdim \fontdimen\@ne\font >\z@
637       \eminnershape \else \itshape \fi
638   \else

```

But if not we use the list to decide how to do emphasis.

We use the current font to check if the declarations have any effect, so even a size change is allowed and identified as a modification (but a color change, for example, isn't). So first we save the current status.

```

639   \edef\em@currfont{\csname\curr@fontshape/\f@size\endcsname}%

```

Then we grab the next element from the list and check if it can be used.

```

640   \expandafter\do@emfont@update\emfontdeclare@clist\do@emfont@update
641   \fi
642 }
643 \def\eminnershape{\upshape}

```

*(End of definition for \em.)*

`\do@emfont@update` We know that the list (if not empty) has at least 2 elements separated by a comma, so we pick up the first in #1 and the rest in #2.

```

644 \def\do@emfont@update#1,#2\do@emfont@update{%

```

First action is to alter the list and move the first entry to the end

```

645   \def\emfontdeclare@clist{#2,#1}%

```

---

<sup>38</sup>Maybe we should not add `\emforce` but allow that case to be skipped as well. Of course, that might result in an endless loop if somebody defines a sequence without any font change and without `\emforce` but ...

Then we execute the current declaration. Appending `\selectfont` means one can write just `\fontshape{it}` and that works then too.

```
646 % \typeout{Use: \detokenize{#1}}%
647 #1\selectfont
```

We then compare the current font with our saved version, but with a slight twist: we add `\em@force` at the end of the name. Normally this is empty so has no effect but if there was an `\emforce` as part of `#1` it will append a `/` to the font name (making it invalid) thus this will then always fail the test.

If the test fails we are done and the declarations will be used. Otherwise we will try the next declaration in the sequence.

```
648 \expandafter\ifx\csname \curr@fontshape/\f@size\em@force
```

For the comparison with `\ifx` we have to expand `\em@currfont` once as the relevant info is inside.

```
649 \expandafter\endcsname
650 \em@currfont
651 \expandafter\do@emfont@update\emfontdeclare@clist\do@emfont@update
```

If `\emforce` was used, we have to undo its effect:

```
652 \else
653 \let\em@force\@empty
654 \fi
655 }
```

(End of definition for `\do@emfont@update`.)

`\emforce` The definition of `\emforce` is simple: change `\em@force` to make the above test always  
`\em@force` invalid.

```
656 \protected\def\emforce{\def\em@force{}}
657 \let\em@force\@empty
658 </2ekernel | latexrelease>
659 <latexrelease>\EndIncludeInRelease
```

(End of definition for `\emforce` and `\em@force`.)

`\em` These are the older definitions for `\em`, prior to 2020.

`\emminnershape` We also have to define the *emphasize* font change command (i.e. `\em`). This command will look is the current font is sloped (i.e. has a positive `\fontdimen1`) and will then select either `\upshape` or `\itshape`.

```
660 <latexrelease>\IncludeInRelease{2015/01/01}{\DeclareEmphSequence}{Nested emph}%
661 <latexrelease>\let\DeclareEmphSequence\@undefined

673 <latexrelease>\IncludeInRelease{0000/00/00}{\DeclareEmphSequence}{Nested emph}%
```

```

674 <latexrelease>\DeclareRobustCommand\em
675 <latexrelease>      {\@nomath\em \ifdim \fontdimen\@ne\font >\z@
676 <latexrelease>      \upshape \else \itshape \fi}%
677 <latexrelease>\let\eminnershape\@undefined
678 <latexrelease>\EndIncludeInRelease
679 <*2ekernel>

```

*(End of definition for \em and \eminnershape.)*

**\not@math@alphabet** This function generates an error message when it is called in math mode. The same function should be defined in `newfont.sty`.

```

680 \def\not@math@alphabet#1#2{%
681     \relax
682     \ifmmode
683         \@latex@error{Command \noexpand#1invalid in math mode}%
684         {%
685             Please
686             \ifx#2\relax
687                 define a new math alphabet^^J%
688                 if you want to use a special font in math mode%
689             \else

```

We have to a `\noexpand` below to prevent expansion of `#2`. In case of `#1` we can omit this (due to the current definition of robust commands since they do come out right there :-).

```

690             use the math alphabet \noexpand#2instead of
691             the #1command%
692         \fi
693         .
694     }%
695 \fi}

```

*(End of definition for \not@math@alphabet.)*

Finally we provide two abbreviations to switch to the L<sup>A</sup>T<sub>E</sub>X *versions*.

```

696 \DeclareRobustCommand\boldmath{\@nomath\boldmath
697     \mathversion{bold}}
698 \DeclareRobustCommand\unboldmath{\@nomath\unboldmath
699     \mathversion{normal}}

```

Here we switch to the default math version by defining the internal macro `\math@version`. We dare not to call `\mathversion` at this place because this would call `\glb@settings`.

```

700 \def\math@version{normal}

```

### 3.1 Legacy

We start by defining a few macros that are part of standard L<sup>A</sup>T<sub>E</sub>X's user interface. The use of these functions is not encouraged, but they will allow to process older documents without changes to the source.

**\newfont**

```

701 \def\newfont#1#2{\@ifdefinable#1{\font#1=#2\relax}}

```

*(End of definition for \newfont.)*

`\symbol`

```
702 </2ekernel>
703 <*2ekernel | latexrelease>
704 <latexrelease>\IncludeInRelease{2020/10/01}%
705 <latexrelease>{\symbol}{XeTeX change for math}%
706 \ifdefined\XeTeXversion
707 \DeclareRobustCommand\symbol[1]{\Ucharcat#1 12\relax}
708 \else
709 \DeclareRobustCommand\symbol[1]{\char#1\relax}
710 \fi
711 </2ekernel | latexrelease>
712 <latexrelease>\EndIncludeInRelease
713 <latexrelease>\IncludeInRelease{0000/00/00}%
714 <latexrelease>{\symbol}{XeTeX change for math}%
715 <latexrelease>
716 <latexrelease>\DeclareRobustCommand\symbol[1]{\char#1\relax}
717 <latexrelease>
718 <latexrelease>\EndIncludeInRelease
719 <*2ekernel>
```

*(End of definition for \symbol.)*

### 3.2 Miscellaneous

`\@setfontsize` This abbreviation is used by L<sup>A</sup>T<sub>E</sub>X's user level size changing commands, such as `\large`.

`\@setsize` 720 `\def\@setfontsize#1#2#3{\@nomath#1%`

For the benefit of people relying on keeping the name of the current font command saved in `\@currsize` we define it. To ensure that `\@setfontsize` keeps being robust we omit this assignment during times where `\protect` differs from `\@typeset@protect`.

```
721 \ifx\protect\@typeset@protect
722 \let\@currsize#1%
723 \fi
724 \fontsize{#2}{#3}\selectfont}
```

For compatibility we also define `\@setsize` the 209 command

```
725 <*compat>
726 \def\@setsize#1#2#3#4{\@setfontsize#1{#4}{#2}}
727 </compat>
```

*(End of definition for \@setfontsize and \@setsize.)*

`\hexnumber@` To set up L<sup>A</sup>T<sub>E</sub>X's special math character definitions we first provide a macro to generate hexadecimal numbers. It is a rather simple `\ifcase`.

```
728 \def\hexnumber@#1{\ifcase\number#1
729 0\or 1\or 2\or 3\or 4\or 5\or 6\or 7\or 8\or
730 9\or A\or B\or C\or D\or E\or F\fi}
```

*(End of definition for \hexnumber@.)*

`\nfss@text` In its simplest form `\nfss@text` is an `\mbox`. This will produce unbreakable text outside math and inside math you will get text with the same fonts as outside. The only drawback is that such item won't change sizes in subscripts. But this behavior can be easily changed.

With the `amstex` style option one will get a sub style called `amstext` which will redefine the `\nfss@text` macro to produce correct text in all sizes.

We have to use `\def` instead of the shorter `\let` since `\mbox` is undefined when we reach this point.

```
731 \def\nfss@text#1{\mbox{#1}}
```

(End of definition for `\nfss@text`.)

`\copyright` The definition of `\copyright` was changed so that it works in other type styles, and to make it robust. We leave the family untouched so that the copyright notice will come out differently if a different font family is in use. This command is commented out, since it is now defined in `ltoutenc.dtx`.

```
732 %\DeclareRobustCommand\copyright
733 %    {\ooalign{\hfil
734 %        \raise.07ex\hbox{\mdseries\upshape c}\hfil\crcr
735 %        \mathhexbox20D}}}
```

(End of definition for `\copyright`.)

`\normalfont` The macro `\reset@font` is used in L<sup>A</sup>T<sub>E</sub>X to switch to a standard font, in order to initialize the current font in situations where typesetting is done in a new visual context (e.g. in a footnote). We define it here to allow the test for the new L<sup>A</sup>T<sub>E</sub>X version above but nevertheless are able to run all kind of mixtures.

The user interface name for `\reset@font` is `\normalfont`:

```
736 </2ekernel>
737 <*2ekernel|latexrelease>
738 <latexrelease>\IncludeInRelease{2025/11/01}%
739 <latexrelease>                {\normalfont}{Support meta family}%
740 \DeclareRobustCommand\normalfont{%
```

Instead of calling `\usefont`, as it was done in the past, we inline the code from `\usefont` as we want to add the hook before `\selectfont`, but after all the font attributes are set.

```
741 \fontencoding\encodingdefault
742 \edef\f@family{\familydefault}%
743 \edef\f@series{\seriesdefault}%
744 \edef\f@shape{\shapedefault}%
```

Now that `\f@family` is set we can update the meta family macro.

```
745 \set@current@meta@family
```

Any earlier `\fontseries`, etc. should be canceled and we should switch unconditionally to the requested font face so we drop any code that may have been stored in `\delayed@f@adjustment`.

```
746 \let\delayed@f@adjustment\@empty
747 \UseHook{normalfont}%
748 \selectfont}
749 \let\reset@font\normalfont
```

(End of definition for `\normalfont` and `\reset@font`.)

`\set@current@meta@family` This macros determines the current meta family by comparing the current family in `\f@family` with the various document font defaults, e.g., `\rmdefault`.

```
750 \def\set@current@meta@family {%
```

Because these defaults can be set by the user and may contain the family name indirectly, we first expand them to ensure we do not get false negatives.

```

751 \edef\rmdef@ult{\rmdefault}%
752 \ifx\f@family\rmdef@ult
753 \def\@currentmetafamily{rm}%
754 \else
755 \ifx\f@family\sfdef@ult
756 \def\@currentmetafamily{sf}%
757 \else
758 \ifx\f@family\ttdef@ult
759 \def\@currentmetafamily{tt}%
760 \else
761 \def\@currentmetafamily{??}%
762 \fi
763 \fi
764 \fi
765 }

```

(End of definition for \set@current@meta@family.)

```

```

`\fontfamily` One place where the current meta family should be set is `\fontfamily`, which is why we defined it here after the definition of `\set@current@meta@family` in this file.

```

834 </2ekernel>
835 <*2ekernel | latexrelease>
836 <latexrelease>\IncludeInRelease{2025/11/01}%
837 <latexrelease>          {\fontfamily}{Set meta family}%
838 \DeclareRobustCommand\fontfamily[1]
839   {\edef\f@family{#1}\set@current@meta@family}
840 </2ekernel | latexrelease>
841 <latexrelease>\EndIncludeInRelease
842 <latexrelease>\IncludeInRelease{0000/00/00}%
843 <latexrelease>          {\fontfamily}{Set meta family}%
844 <latexrelease>
845 <latexrelease>\DeclareRobustCommand\fontfamily[1]{\edef\f@family{#1}}
846 <latexrelease>\EndIncludeInRelease
847 <*2ekernel>

```

*(End of definition for \fontfamily.)*

We left out the special L<sup>A</sup>T<sub>E</sub>X fonts which are not automatically included in the base version of the font selection since these fonts contain only a few characters which are also included in the AMS fonts so anybody who is using these fonts doesn't need them. But for compatibility reasons we will define these symbols.

```

848 \def\not@base#1{\@latex@error
849   {Command \noexpand#1not provided in base LaTeX2e}%
850   {Load the latexsym or the amsfonts package to
851     define this symbol}}
852 \def\mho{\not@base\mho}
853 \def\Join{\not@base\Join}
854 \def\Box{\not@base\Box}
855 \def\Diamond{\not@base\Diamond}
856 \def\leadsto{\not@base\leadsto}
857 \def\squsubset{\not@base\squsubset}
858 \def\sqsupset{\not@base\sqsupset}
859 \def\lhd{\not@base\lhd}
860 \def\unlhd{\not@base\unlhd}
861 \def\rhd{\not@base\rhd}
862 \def\unrhd{\not@base\unrhd}

```

We now initialize all variables set by `\DeclareErrorFont`. These values are not really important since they will be overwritten later on by the definition in `fontdef.ltx`.

However, if `fontdef.cfg` is corrupted then at least a hopefully suitable error font is present.

```

863 \DeclareErrorFont{OT1}{cmr}{m}{n}{10}  %% don't modify this setting
864                                         %% overwrite it in fontdef.cfg
865                                         %% if necessary

```

We also set some default values for `\f@family` etc. Note that we don't yet have any encodings that comes later. In the past this was implicitly done by `\DeclareErrorFont`.

```

866 \def\f@family{cmr}          % can't use \fontfamily at this point as
867                             % defaults aren't set up yet

```

Previously the default values for series and shape were set by calling `\fontseries` and `\fontshape`, but their action is now delayed until `\selectfont` which isn't called inside the format (to avoid unnecessarily loading a font that may never get used). We therefore have to set `\f@series` and `\f@shape` directly instead.

```

868 \def\f@series{m}            % \fontseries{m}
869 \def\f@shape{n}             % \fontshape{n}
870 \fontsize{10}{10}

```

The initial `fontenc` package load list. This will get overwritten in `fonttext` and is only provided in case an old `fonttext.cfg` does not define the command:

```

871 \def\@fontenc@load@list{\@elt{T1,OT1}}

```

We now load the customizable parts of NFSS.

```

872 \InputIfFileExists{fonttext.cfg}
873   {\typeout{=====^^J%
874             ^^J%
875             Local config file fonttext.cfg used^^J%
876             ^^J%
877             =====}%}

```

```

878         \def\@addtofilelist##1{\xdef\@filelist{\@filelist,##1}}%
879     }
880     {\input{fonttext.ltx}}
881 \let\@addtofilelist\@gobble

Ditto for math although I don't think that we will get a lot of customization :-)

882 \InputIfFileExists{fontmath.cfg}
883     {\typeout{=====^^J%
884             ^^J%
885             Local config file fontmath.cfg used^^J%
886             ^^J%
887             =====}%
888     \def\@addtofilelist##1{\xdef\@filelist{\@filelist,##1}}%
889     }
890     {\input{fontmath.ltx}}
891 \let\@addtofilelist\@gobble

```

Then we preload several fonts. This file might be customized *without* changing the behavior of the format (i.e. necessary font definitions will be loaded at runtime if they are not preloaded). This is done in the file `preload.ltx`.

```

892 \InputIfFileExists{preload.cfg}
893     {\typeout{=====^^J%
894             ^^J%
895             Local config file preload.cfg used^^J%
896             ^^J%
897             =====}%
898     \def\@addtofilelist##1{\xdef\@filelist{\@filelist,##1}}%
899     }
900     {\input{preload.ltx}}
901 \let\@addtofilelist\@gobble

```

`\seriesdefault` After `\seriesdefault` got defined inside `fonttext.ltx` or a `.cfg` file overwriting it, we alter its value by appending `\@empty` to it. This will vanish if expanded but allows us to check if the default gets altered (even to the same value) in the document preamble. All we have to do is to save the current value somewhere and later compare the two. For this we use `\seriesdefault@kernel`.

```

902 \expandafter\def\expandafter\seriesdefault\expandafter{\seriesdefault\@empty}
903 \let\seriesdefault@kernel\seriesdefault

```

(End of definition for `\seriesdefault` and `\seriesdefault@kernel`.)

`\@acci` We also save the values of some accents in `\@acci`, `\@accii` and `\@acciii` so they can  
`\@accii` be restored by a `minipage` inside a `tabbing` environment.  
`\@acciii` 904 \let\@acci\ ' \let\@accii\ ' \let\@acciii\=

(End of definition for `\@acci`, `\@accii`, and `\@acciii`.)

`\cal` Here were the two old `\alphabet identifiers`.

`\mit` (End of definition for `\cal` and `\mit`.)

```

905 \</2ekernel>

```

# File 30

## fontdef.dtx

### 1 Introduction

This file is used to generate the files `fonttext.ltx` (text font declarations) and `fontmath.ltx` (math font declarations), which are used during the format generation. It contains the declaration of the standard text encodings used at the site as well as a minimal subset of font shape groups that NFSS will look at to ensure that the specified encodings are valid.

The math part contains the setup for math encodings as well as the default math symbol declarations that belong to the encoding.

It is possible to change this setup (by using other fonts, or defaults) without losing the ability to process documents written at other sites. Portability in this sense means that a document will compile without errors. It does not mean, however, that identical output will be produced. For this it is necessary that the distributed setup is used at both installations.

### 2 Customization

You are not allowed to change this source file! If you want to change the default encodings and/or the font shape groups preloaded you should create a copy of `fonttext.ltx` under the name `fonttext.cfg` and change this copy. If  $\text{\LaTeX}$  2<sub>ε</sub> finds a file of this name it will use it, otherwise it uses the standard file which is `fontdef.ltx`.

If you don't plan to use Computer Modern much or at all, it might (!) be a good idea to make your own `fonttext.cfg`. Look at the comments below (docstrip module 'text') to see what should go into such a file.

To change the math font setup use a copy of `fontmath.ltx` under the name `fontmath.cfg` and change this copy. However, dealing with this interface is even more a job for an expert than changing the text font setup — in short, we don't encourage either.

**Warning:** please note that we don't support customised  $\text{\LaTeX}$  versions. Thus, before sending in a bug report please try your test file with a  $\text{\LaTeX}$  format which is not customised and send in the log from that version (unless the problem goes away).

Please note: the following standard encodings have to be defined in all local variants of `font....cfg` to guarantee that all  $\text{\LaTeX}$  installations behave in the same way.

T1	Cork $\text{\TeX}$ text encoding
OT1	old $\text{\TeX}$ text encoding
U	unknown encoding
OML	old $\text{\TeX}$ math letters encoding
OMS	old $\text{\TeX}$ math symbols encoding
OMX	old $\text{\TeX}$ math extension symbols encoding
TU	Unicode

Notice that some of these encodings are ‘old’ in the sense that we hope that they will be superseded soon by encoding standards defined by the T<sub>E</sub>X user community. Therefore this set of default encodings may change in the future.

The first candidate is OT1 which will soon be replaced by T1, the official T<sub>E</sub>X text encoding.

**Warning:** If you add additional encodings to this file there is no guarantee any longer that files processable at your installation will also be processable at other installations. Thus, if you make use of such an encoding in your document, e.g. if you intend to typeset in Cyrillic (OT2 encoding), you need to specify this encoding in the preamble of your document prior to sending it to another installation. Once the encoding is specified in that place in your document, the document is processable at all L<sup>A</sup>T<sub>E</sub>X installations (provided they have suitable fonts installed).

For this reason we suggest that you define a short package file that sets up an additional encoding used at your site (rather than putting the encoding into this file) since this package can easily be shipped with your document.

### 3 The docstrip modules

The following modules are used to direct **docstrip** in generating external files:

driver	produce a documentation driver file
text	produce the file <b>fonttext.ltx</b>
math	produce the file <b>fontmath.ltx</b>
cfgtext	produce a dummy <b>fonttext.cfg</b> file
cfgmath	produce a dummy <b>fontmath.cfg</b> file

A typical **docstrip** command file would then have entries like:

```
generateFile{fonttext.ltx}{t}{\from{fontdef.dtx}{text}}
```

### 4 A driver for this document

The next bit of code contains the documentation driver file for T<sub>E</sub>X, i.e. the file that will produce the documentation you are currently reading. It will be extracted from this file by the DOCSTRIP program.

```
1 <*driver>
2 \documentclass{ltxdoc}
3 \GetFileInfo{fontdef.dtx}
4 \begin{document}
5   \DocInput{fontdef.dtx}
6 \end{document}
7 </driver>
```

### 5 The fonttext.ltx file

The identification is done earlier on with a \ProvidesFile declaration.

```
8 <*text>
9 \typeout{=== Don't modify this file, use a .cfg file instead ===^~J}
```

## 5.1 Encodings

This file declares the standard encodings for text and math fonts. All others should be declared in packages or in the documents directly.

For every text encoding there are normally a number of encoding specific commands, e.g. accents, special characters, etc. (The definition for such a command might have to change when the encoding is changed, because the character is in a different position, or not available at all, or the accent is produced in a different way.) This is handled by a general mechanism which is described in `ltoutenc.dtx`.

By convention, text encoding specific declarations, including the `\DeclareFontEncoding` declaration, are kept in separate file of the form `<enc>enc.def`, e.g. `ot1enc.def`. This allows other applications to make use of the declarations as well.

Similar to the default encoding, the loading of the encoding files for the two major text encodings shouldn't be changed. In particular, the `inputenc` package depends on this.

```
10 \input {omlenc.def}
11 \input {omsenc.def}
```

Documents containing a lot of accented characters should really be using T1 fonts. We therefore load this after OT1 so that T1 encoding specific commands are executed as fast as possible (encoding files are no longer reloaded in `fontenc`).

```
12 \input {ot1enc.def}
13 \input {t1enc.def}
14 \input {ts1enc.def}

15 \ifx\Umathcode\@undefined
```

We then set the default text font encoding. This will hopefully change some day to T1. This setting should *not* be changed to produce a portable format.

```
16 \fontencoding{OT1}

The initial fontenc package load list if an 8-bit TEX engine is used:
17 \def\@fontenc@load@list{\@elt{T1,OT1}}
18 \def\rmsubstdefault{cmr}
19 \def\sfsubstdefault{cmss}
20 \def\ttsubstdefault{cmtt}
21 \LoadFontDefinitionFile{TS1}{cmr}

22 \else
```

Unicode.

```
23 \input {tuenc.def}
24 \fontencoding{TU}

The initial fontenc package load list if a Unicode engine is used:
25 \def\@fontenc@load@list{\@elt{TU}}
26 \DeclareFontSubstitution{TU}{lmr}{m}{n}
27 \LoadFontDefinitionFile{TU}{lmr}
28 \LoadFontDefinitionFile{TU}{lmss}
29 \LoadFontDefinitionFile{TU}{lmtt}

30 \def\rmsubstdefault{lmr}
31 \def\sfsubstdefault{lmss}
32 \def\ttsubstdefault{lmtt}
33 \LoadFontDefinitionFile{TS1}{lmr}
```

```
34 \DeclareFontSubstitution{TU}{lmr}{m}{n}
```

End of Unicode branch.

```
35 \fi
```

If different encodings for text fonts are in use one could put the common setup into `\DeclareFontEncodingDefaults`. There is now a better mechanism so using this interface is discouraged!

```
36 \DeclareFontEncodingDefaults{}{}
```

The default font substitution for an encoding is defined in the corresponding `...enc.def` file so for OT1, T1, and TS1 this is already defined.

```
37 %\DeclareFontSubstitution{T1}{cmr}{m}{n}
```

```
38 %\DeclareFontSubstitution{OT1}{cmr}{m}{n}
```

```
39 %\DeclareFontSubstitution{TS1}{cmr}{m}{n}
```

This release of L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> assumes that the ec fonts are available. It is possible to change this to point to some other font family (e.g., Times with the appropriate encoding if it is available) without making documents non-portable. However, in such a case documents will produce different page breaks at other sites. The substitution defaults can all be changed without losing portability as long as there are font shape definitions for the selected substitutions.

For every encoding declaration, L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> will try to verify that the given substitution information makes sense, i.e. that it is impossible to go into an endless loop if font substitution happens. This is done at the moment the `\begin{document}` is encountered. L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> will then check that for every encoding the substitution defaults form a valid font shape group, which means that it will check if there is a `\DeclareFontShape` declaration for this combination. We will therefore load the corresponding `.fd` files now. If we don't do this they would be loaded at verification time (i.e. at `\begin{document}`) which would delay processing unnecessarily.

**Warning:** Please note that this means that you have to regenerate the format whenever you change any of these `.fd` files since L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> will not read `.fd` files if it already knows about the encoding/family combination.

The `\nfss@catcodes` ensures that white space is ignored in any definitions made in the fd files.

```
40 \begingroup
```

```
41 \nfss@catcodes
```

```
42 \input {t1cmr.fd}
```

```
43 \input {ot1cmr.fd}
```

```
44 \input {ts1cmr.fd}
```

```
45 \endgroup
```

We also load some other font definition files which are normally needed in a document. This is only done for processing speed and you can comment the next two lines out to save some memory. If necessary these files are then loaded when your document is processed. (Loading `.fd` files is a less drastic step compared to preloading fonts because the number of fonts is limited 255 at (nearly) every T<sub>E</sub>X installation, while the amount of main memory is not a limiting factor at most installations.)

```
46 \begingroup
```

```
47 \nfss@catcodes
```

```
48 \input {t1cmss.fd}
```

```

49 \input {t1cmtt.fd}
50 \input {ot1cmss.fd}
51 \input {ot1cmtt.fd}

52 \input {ts1cmss.fd}
53 \input {ts1cmtt.fd}
54 \endgroup

```

Even though Unicode engines default to `lm` load `ts1cmr` as this may be used for fallback for TS1 encoding.

We now load it in all engines above, so the next lines are no longer necessary. We keep them here if we stop loading other `fd` files in Unicode engines.

```

55 %\ifx\Umathcode\@undefined\else
56 %\begingroup
57 %\nfss@catcodes
58 %\input {ts1cmr.fd}
59 %\endgroup
60 %\fi

```

Even with all the precautions it is still possible that NFSS will run into problems, for example, when a `.fd` file contains corrupted data. To guard against such cases NFSS has a very low-level fallback font that is installed with the following line.

```

61 \DeclareErrorFont{OT1}{cmr}{m}{n}{10}

```

This means, “if everything else fails use Computer Modern Roman normal shape at 10pt in the old text encoding”. You can change the font used but the encoding should be the same as the one specified with `\fontencoding` above.

## 5.2 Defaults

To allow the use of `\rmfamily`, `\sffamily`, etc. in documents even if non-standard families are used we provide nine macros which hold the name of the corresponding families, series, and so on. This makes it easy to use other font families (like Times Roman, etc.). One simply has to redefine these defaults.

All these hooks have to be defined in this file but you can change their meaning (except for `\encodingdefault`) without making documents non-portable.

```

\encodingdefault The following three definitions set up the meaning for \rmfamily, \sffamily, and
\rmdefault      \ttfamily.
\sfdefault
\ttdefault
62 \ifx\Umathcode\@undefined
63 \newcommand\encodingdefault{OT1}
64 \newcommand\rmdefault{cmr}
65 \newcommand\sfdefault{cmss}
66 \newcommand\ttdefault{cmtt}
67 \else
68 \newcommand\encodingdefault{TU}
69 \newcommand\rmdefault{lmr}
70 \fontfamily{\rmdefault}
71 \newcommand\sfdefault{lmss}
72 \newcommand\ttdefault{lm tt}
73 \fi
74 \</text>
75 \<latexrelease>\IncludeInRelease{2017/01/01}%
76 \<latexrelease>          {\encodingdefault}{TU encoding default}%

```

```

77 <latexrelease>\ifx\Umathcode\@undefined
78 <latexrelease>\renewcommand\encodingdefault{OT1}
79 <latexrelease>\fontencoding{\encodingdefault}
80 <latexrelease>\renewcommand\rmdefault{cmr}
81 <latexrelease>\fontfamily{\rmdefault}
82 <latexrelease>\renewcommand\sfddefault{cmss}
83 <latexrelease>\renewcommand\ttdefault{cmtt}
84 <latexrelease>\else
85 <latexrelease>\renewcommand\encodingdefault{TU}
86 <latexrelease>%done in everyjob\fontencoding{\encodingdefault}
87 <latexrelease>\renewcommand\rmdefault{lmr}
88 <latexrelease>\fontfamily{\rmdefault}
89 <latexrelease>\renewcommand\sfddefault{lmss}
90 <latexrelease>\renewcommand\ttdefault{lmtt}
91 <latexrelease>\fi
92 <latexrelease>\EndIncludeInRelease
93 <latexrelease>\IncludeInRelease{0000/00/00}%
94 <latexrelease>          {\encodingdefault}{TU encoding default}%
95 <latexrelease>\fontencoding{OT1}
96 <latexrelease>\renewcommand\encodingdefault{OT1}
97 <latexrelease>\fontencoding{\encodingdefault}
98 <latexrelease>\renewcommand\rmdefault{cmr}
99 <latexrelease>\fontfamily{\rmdefault}
100 <latexrelease>\renewcommand\sfddefault{cmss}
101 <latexrelease>\renewcommand\ttdefault{cmtt}
102 <latexrelease>\EndIncludeInRelease
103 <*text>

```

*(End of definition for \encodingdefault and others.)*

**\bfdefault** Series changing commands are influenced by the following hooks.  
**\mddefault**

```

104 \newcommand\bfdefault{b} % overwritten below (for rollback)
105 \newcommand\mddefault{m} % overwritten below (for rollback)

```

*(End of definition for \bfdefault and \mddefault.)*

**\itdefault** Shape changing commands use the following hooks.  
**\sldefault**

```

106 \newcommand\itdefault{it}
107 \newcommand\sldefault{sl}
108 \newcommand\scdefault{sc}
109 \newcommand\updefault{up} % overwritten below (for rollback)

```

*(End of definition for \itdefault and others.)*

```

110 </text>
111 <*text | latexrelease>
112 <latexrelease>\IncludeInRelease{2020/02/02}%
113 <latexrelease>          {\updefault}{font defaults change}%
114 \renewcommand\updefault{up}

```

We append \@empty to the series value so that we can detect if it got changed via \def or \renewcommand later.

```

115 \renewcommand\bfdefault{b\@empty}
116 \renewcommand\mddefault{m\@empty}

```

```

117 \let\bfdefault@previous\bfdefault
118 \let\mddefault@previous\mddefault
119 </text | latexrelease>
120 <latexrelease>\EndIncludeInRelease
121 <latexrelease>\IncludeInRelease{0000/00/00}%
122 <latexrelease>                {\updefault}{font defaults change}%
123 <latexrelease>
124 <latexrelease>\renewcommand\updefault{n}
125 <latexrelease>\renewcommand\bfdefault{bx}
126 <latexrelease>
127 <latexrelease>\let\bfdefault@previous\undefined
128 <latexrelease>\let\mddefault@previous\undefined
129 <latexrelease>\EndIncludeInRelease
130 <*text>

```

`\familydefault` Finally we have the hooks that describe the behaviour of the `\normalfont` command.  
`\seriesdefault` To stay portable, the definition of `\encodingdefault` should *not* be changed and should  
`\shapedefault` match the setting above for `\fontencoding`. All other values can be set according to your taste.

```

131 \newcommand\familydefault{\rmdefault}
132 \newcommand\seriesdefault{\mddefault}

```

In previous releases `\shapedefault` pointed to `\updefault` which resolved to `n`, but these days that is no longer the case (and `up` is wrong when you want to do a reset. So we now use `n` explicitly.

```

133 \newcommand\shapedefault{n}

```

(End of definition for `\familydefault`, `\seriesdefault`, and `\shapedefault`.)

This finishes the low-level setup in `fonttext.ltx`.

```

134 </text>

```

## 6 The fontmath.ltx file

The identification is done earlier on with a `\ProvidesFile` declaration.

```

135 <*math>
136 \typeout{=== Don't modify this file, use a .cfg file instead ===^J}

```

### 6.1 The font encodings used

```

137 \DeclareFontEncoding{OML}{-}{-}
138 \DeclareFontEncoding{OMS}{-}{-}
139 \DeclareFontEncoding{OMX}{-}{-}

```

Finally a declaration for `U` encoding which serves for all fonts that do not fit standard encodings. For math this sets up `\noaccents@` providing for AMS- $\LaTeX$ . This macro is used therein to handle accented characters if they are not supported by the font. In other words, if fonts with `U` encoding are used in math, all accents (like from `\breve`) are obtained from some other font that has them.

```

140 \DeclareFontEncoding{U}{-}{\noaccents@}

```

The encodings for math are next:

```

141 \DeclareFontSubstitution{OML}{cmm}{m}{it}
142 \DeclareFontSubstitution{OMS}{cmsy}{m}{n}

```

```

143 \DeclareFontSubstitution{OMX}{cmex}{m}{n}
144 \DeclareFontSubstitution{U}{cmr}{m}{n}
145 \begingroup
146 \nfss@catcodes
147 \input {omlcmm.fd}
148 \input {omscmsy.fd}
149 \input {omxcmex.fd}
150 \input {ucmr.fd}
151 \endgroup

```

### 6.1.1 Symbolfont and Alphabet declarations

We now define the basic symbol fonts used by L<sup>A</sup>T<sub>E</sub>X. These four symbol fonts must be defined by this file.

It is possible to make the symbol fonts point to other external fonts without losing the ability to process documents written at other sites, as long as one defines the same symbol font names with the same encodings, e.g. `operators` with `OT1` etc. If other encodings are used documents become non-portable. Such a change should therefore be done in a package file.

```

152 \DeclareSymbolFont{operators} {OT1}{cmr} {m}{n}
153 \DeclareSymbolFont{letters} {OML}{cmm} {m}{it}
154 \DeclareSymbolFont{symbols} {OMS}{cmsy}{m}{n}
155 \DeclareSymbolFont{largesymbols}{OMX}{cmex}{m}{n}
156 \SetSymbolFont{operators}{bold}{OT1}{cmr} {bx}{n}
157 \SetSymbolFont{letters} {bold}{OML}{cmm} {b}{it}
158 \SetSymbolFont{symbols} {bold}{OMS}{cmsy}{b}{n}

```

Below are the seven math alphabets which are defined by NFSS. Again they must be defined by this file. However, as before you can change the fonts used without losing portability, but you should be careful when changing the encoding since that may make documents come out wrong.

```

159 \DeclareSymbolFontAlphabet{\mathrm} {operators}
160 \DeclareSymbolFontAlphabet{\mathnormal}{letters}
161 \DeclareSymbolFontAlphabet{\mathcal} {symbols}
162 \DeclareMathAlphabet {\mathbf} {OT1}{cmr}{bx}{n}
163 \DeclareMathAlphabet {\mathsf} {OT1}{cmss}{m}{n}
164 \DeclareMathAlphabet {\mathit}{OT1}{cmr}{m}{it}
165 \DeclareMathAlphabet {\mathtt}{OT1}{cmtt}{m}{n}

```

Given the currently available fonts we cannot bold-en `\mathbf` and `\mathtt` but in principle one could use ‘ultra bold’ or something. The alphabets defined via `\DeclareSymbolFontAlphabet` will change automatically in a new math version if the corresponding symbol font changes.

```

166 \SetMathAlphabet\mathsf{bold}{OT1}{cmss}{bx}{n}
167 \SetMathAlphabet\mathit{bold}{OT1}{cmr}{bx}{it}

```

## 6.2 Math font sizes

The declarations below declare the text, script and scriptscript size to be used for each text font size.

All occurrences of sizes longer than a single character are replaced with the macro name that holds them, saving a number of tokens (but losing a bit of speed, so this may not stay this way).

```

168 \DeclareMathSizes{5}{5}{5}{5}
169 \DeclareMathSizes{6}{6}{5}{5}
170 \DeclareMathSizes{7}{7}{5}{5}
171 \DeclareMathSizes{8}{8}{6}{5}
172 \DeclareMathSizes{9}{9}{6}{5}
173 \DeclareMathSizes{\@xpt}{\@xpt}{7}{5}
174 \DeclareMathSizes{\@xipt}{\@xipt}{8}{6}
175 \DeclareMathSizes{\@xipt}{\@xipt}{8}{6}
176 \DeclareMathSizes{\@xivpt}{\@xivpt}{\@xpt}{7}
177 \DeclareMathSizes{\@xvipt}{\@xvipt}{\@xipt}{\@xpt}
178 \DeclareMathSizes{\@xxpt}{\@xxpt}{\@xivpt}{\@xipt}
179 \DeclareMathSizes{\@xxvpt}{\@xxvpt}{\@xxpt}{\@xvipt}

```

### 6.3 The math symbol assignments

We start by setting up math codes for most of the characters typed in directly from the keyboard. Most of them are normally already setup up in the same way by `IniTeX`. However, we repeat them here to have a complete setup which can be exchanged with another if desired.

#### 6.3.1 The letters

```

180 \DeclareMathSymbol{a}{\mathalpha}{letters}{'a}
181 \DeclareMathSymbol{b}{\mathalpha}{letters}{'b}
182 \DeclareMathSymbol{c}{\mathalpha}{letters}{'c}
183 \DeclareMathSymbol{d}{\mathalpha}{letters}{'d}
184 \DeclareMathSymbol{e}{\mathalpha}{letters}{'e}
185 \DeclareMathSymbol{f}{\mathalpha}{letters}{'f}
186 \DeclareMathSymbol{g}{\mathalpha}{letters}{'g}
187 \DeclareMathSymbol{h}{\mathalpha}{letters}{'h}
188 \DeclareMathSymbol{i}{\mathalpha}{letters}{'i}
189 \DeclareMathSymbol{j}{\mathalpha}{letters}{'j}
190 \DeclareMathSymbol{k}{\mathalpha}{letters}{'k}
191 \DeclareMathSymbol{l}{\mathalpha}{letters}{'l}
192 \DeclareMathSymbol{m}{\mathalpha}{letters}{'m}
193 \DeclareMathSymbol{n}{\mathalpha}{letters}{'n}
194 \DeclareMathSymbol{o}{\mathalpha}{letters}{'o}
195 \DeclareMathSymbol{p}{\mathalpha}{letters}{'p}
196 \DeclareMathSymbol{q}{\mathalpha}{letters}{'q}
197 \DeclareMathSymbol{r}{\mathalpha}{letters}{'r}
198 \DeclareMathSymbol{s}{\mathalpha}{letters}{'s}
199 \DeclareMathSymbol{t}{\mathalpha}{letters}{'t}
200 \DeclareMathSymbol{u}{\mathalpha}{letters}{'u}
201 \DeclareMathSymbol{v}{\mathalpha}{letters}{'v}
202 \DeclareMathSymbol{w}{\mathalpha}{letters}{'w}
203 \DeclareMathSymbol{x}{\mathalpha}{letters}{'x}
204 \DeclareMathSymbol{y}{\mathalpha}{letters}{'y}
205 \DeclareMathSymbol{z}{\mathalpha}{letters}{'z}

206 \DeclareMathSymbol{A}{\mathalpha}{letters}{'A}
207 \DeclareMathSymbol{B}{\mathalpha}{letters}{'B}
208 \DeclareMathSymbol{C}{\mathalpha}{letters}{'C}
209 \DeclareMathSymbol{D}{\mathalpha}{letters}{'D}
210 \DeclareMathSymbol{E}{\mathalpha}{letters}{'E}

```

```

211 \DeclareMathSymbol{F}{\mathalpha}{letters}{'F}
212 \DeclareMathSymbol{G}{\mathalpha}{letters}{'G}
213 \DeclareMathSymbol{H}{\mathalpha}{letters}{'H}
214 \DeclareMathSymbol{I}{\mathalpha}{letters}{'I}
215 \DeclareMathSymbol{J}{\mathalpha}{letters}{'J}
216 \DeclareMathSymbol{K}{\mathalpha}{letters}{'K}
217 \DeclareMathSymbol{L}{\mathalpha}{letters}{'L}
218 \DeclareMathSymbol{M}{\mathalpha}{letters}{'M}
219 \DeclareMathSymbol{N}{\mathalpha}{letters}{'N}
220 \DeclareMathSymbol{O}{\mathalpha}{letters}{'O}
221 \DeclareMathSymbol{P}{\mathalpha}{letters}{'P}
222 \DeclareMathSymbol{Q}{\mathalpha}{letters}{'Q}
223 \DeclareMathSymbol{R}{\mathalpha}{letters}{'R}
224 \DeclareMathSymbol{S}{\mathalpha}{letters}{'S}
225 \DeclareMathSymbol{T}{\mathalpha}{letters}{'T}
226 \DeclareMathSymbol{U}{\mathalpha}{letters}{'U}
227 \DeclareMathSymbol{V}{\mathalpha}{letters}{'V}
228 \DeclareMathSymbol{W}{\mathalpha}{letters}{'W}
229 \DeclareMathSymbol{X}{\mathalpha}{letters}{'X}
230 \DeclareMathSymbol{Y}{\mathalpha}{letters}{'Y}
231 \DeclareMathSymbol{Z}{\mathalpha}{letters}{'Z}

```

### 6.3.2 The digits

```

232 \DeclareMathSymbol{0}{\mathalpha}{operators}{'0}
233 \DeclareMathSymbol{1}{\mathalpha}{operators}{'1}
234 \DeclareMathSymbol{2}{\mathalpha}{operators}{'2}
235 \DeclareMathSymbol{3}{\mathalpha}{operators}{'3}
236 \DeclareMathSymbol{4}{\mathalpha}{operators}{'4}
237 \DeclareMathSymbol{5}{\mathalpha}{operators}{'5}
238 \DeclareMathSymbol{6}{\mathalpha}{operators}{'6}
239 \DeclareMathSymbol{7}{\mathalpha}{operators}{'7}
240 \DeclareMathSymbol{8}{\mathalpha}{operators}{'8}
241 \DeclareMathSymbol{9}{\mathalpha}{operators}{'9}

```

### 6.3.3 Punctuation, brace, etc. keys

```

242 \DeclareMathSymbol{!}{\mathclose}{operators}{"21}
243 \DeclareMathSymbol{*}{\mathbin}{symbols}{"03} % \ast
244 \DeclareMathSymbol{+}{\mathbin}{operators}{"2B}
245 \DeclareMathSymbol{,}{\mathpunct}{letters}{"3B}
246 \DeclareMathSymbol{-}{\mathbin}{symbols}{"00}
247 \DeclareMathSymbol{.}{\mathord}{letters}{"3A}
248 \DeclareMathSymbol{:}{\mathrel}{operators}{"3A}
249 \DeclareMathSymbol{;}{\mathpunct}{operators}{"3B}
250 \DeclareMathSymbol{=}{\mathrel}{operators}{"3D}
251 \DeclareMathSymbol{?}{\mathclose}{operators}{"3F}

```

The following symbols are defined as delimiters below which automatically defines them as math symbols.

```

252 %\DeclareMathSymbol{(\mathopen}{operators}{"28}
253 %\DeclareMathSymbol{)}{\mathclose}{operators}{"29}
254 %\DeclareMathSymbol{/}{\mathord}{letters}{"3D}
255 %\DeclareMathSymbol{[}{\mathopen}{operators}{"5B}
256 %\DeclareMathSymbol{]}{\mathclose}{operators}{"5D}
257 %\DeclareMathSymbol{|}{\mathord}{symbols}{"6A}

```

```

258 %\DeclareMathSymbol{<}{\mathrel}{letters}{"3C}
259 %\DeclareMathSymbol{>}{\mathrel}{letters}{"3E}

```

Should all of the following being activated by default? Probably not.

```

260 %\DeclareMathSymbol{\{}{\mathopen}{symbols}{"66}
261 %\DeclareMathSymbol{\}}{\mathclose}{symbols}{"67}
262 %\DeclareMathSymbol{\}\}{\mathord}{symbols}{"6E} % \backslash
263 \mathcode'\ =8000 % \space
264 \mathcode'\ ' =8000 % ^\prime
265 \mathcode'\_ =8000 % \_

```

### 6.3.4 Delimitercodes for characters

[to be completed]

Finally, `InitEX` sets all `\delcode` values to -1, except `\delcode' = 0`

```

266 \DeclareMathDelimiter{()}{\mathopen}{operators}{"28}{largesymbols}{"00}
267 \DeclareMathDelimiter{)}{\mathclose}{operators}{"29}{largesymbols}{"01}
268 \DeclareMathDelimiter{[]}{\mathopen}{operators}{"5B}{largesymbols}{"02}
269 \DeclareMathDelimiter{[]}{\mathclose}{operators}{"5D}{largesymbols}{"03}

```

The next two are considered to be relations when not used in the context of a delimiter! And worse, they do even represent different glyphs when being used as delimiter and not as delimiter. This is a user level syntax inherited from plain `TEX`. Therefore we explicitly redefine the math symbol definitions for these symbols afterwards.

```

270 \DeclareMathDelimiter{<}{\mathopen}{symbols}{"68}{largesymbols}{"0A}
271 \DeclareMathDelimiter{>}{\mathclose}{symbols}{"69}{largesymbols}{"0B}
272 \DeclareMathSymbol{<}{\mathrel}{letters}{"3C}
273 \DeclareMathSymbol{>}{\mathrel}{letters}{"3E}

```

And here is another case where the non-delimiter version produces a glyph different from the delimiter version.

```

274 \DeclareMathDelimiter{/}{\mathord}{operators}{"2F}{largesymbols}{"0E}
275 \DeclareMathSymbol{/}{\mathord}{letters}{"3D}

276 \DeclareMathDelimiter{|}{\mathord}{symbols}{"6A}{largesymbols}{"0C}
277 \expandafter\DeclareMathDelimiter\@backslashchar
278 \mathord}{symbols}{"6E}{largesymbols}{"0F}

```

N.B. `{` and `}` should NOT get delcodes; otherwise parameter grouping fails!

## 6.4 Symbols accessed via control sequences

### 6.4.1 Greek letters

```

279 \DeclareMathSymbol{\alpha}{\mathord}{letters}{"0B}
280 \DeclareMathSymbol{\beta}{\mathord}{letters}{"0C}
281 \DeclareMathSymbol{\gamma}{\mathord}{letters}{"0D}
282 \DeclareMathSymbol{\delta}{\mathord}{letters}{"0E}
283 \DeclareMathSymbol{\epsilon}{\mathord}{letters}{"0F}
284 \DeclareMathSymbol{\zeta}{\mathord}{letters}{"10}
285 \DeclareMathSymbol{\eta}{\mathord}{letters}{"11}
286 \DeclareMathSymbol{\theta}{\mathord}{letters}{"12}
287 \DeclareMathSymbol{\iota}{\mathord}{letters}{"13}
288 \DeclareMathSymbol{\kappa}{\mathord}{letters}{"14}
289 \DeclareMathSymbol{\lambda}{\mathord}{letters}{"15}
290 \DeclareMathSymbol{\mu}{\mathord}{letters}{"16}
291 \DeclareMathSymbol{\nu}{\mathord}{letters}{"17}

```

```

292 \DeclareMathSymbol{\xi}{\mathord}{letters}{18}
293 \DeclareMathSymbol{\pi}{\mathord}{letters}{19}
294 \DeclareMathSymbol{\rho}{\mathord}{letters}{1A}
295 \DeclareMathSymbol{\sigma}{\mathord}{letters}{1B}
296 \DeclareMathSymbol{\tau}{\mathord}{letters}{1C}
297 \DeclareMathSymbol{\upsilon}{\mathord}{letters}{1D}
298 \DeclareMathSymbol{\phi}{\mathord}{letters}{1E}
299 \DeclareMathSymbol{\chi}{\mathord}{letters}{1F}
300 \DeclareMathSymbol{\psi}{\mathord}{letters}{20}
301 \DeclareMathSymbol{\omega}{\mathord}{letters}{21}
302 \DeclareMathSymbol{\varepsilon}{\mathord}{letters}{22}
303 \DeclareMathSymbol{\vartheta}{\mathord}{letters}{23}
304 \DeclareMathSymbol{\varpi}{\mathord}{letters}{24}
305 \DeclareMathSymbol{\varrho}{\mathord}{letters}{25}
306 \DeclareMathSymbol{\varsigma}{\mathord}{letters}{26}
307 \DeclareMathSymbol{\varphi}{\mathord}{letters}{27}
308 \DeclareMathSymbol{\Gamma}{\mathalpha}{operators}{00}
309 \DeclareMathSymbol{\Delta}{\mathalpha}{operators}{01}
310 \DeclareMathSymbol{\Theta}{\mathalpha}{operators}{02}
311 \DeclareMathSymbol{\Lambda}{\mathalpha}{operators}{03}
312 \DeclareMathSymbol{\Xi}{\mathalpha}{operators}{04}
313 \DeclareMathSymbol{\Pi}{\mathalpha}{operators}{05}
314 \DeclareMathSymbol{\Sigma}{\mathalpha}{operators}{06}
315 \DeclareMathSymbol{\Upsilon}{\mathalpha}{operators}{07}
316 \DeclareMathSymbol{\Phi}{\mathalpha}{operators}{08}
317 \DeclareMathSymbol{\Psi}{\mathalpha}{operators}{09}
318 \DeclareMathSymbol{\Omega}{\mathalpha}{operators}{0A}

```

#### 6.4.2 Ordinary symbols

```

319 \DeclareMathSymbol{\aleph}{\mathord}{symbols}{40}
320 \DeclareMathSymbol{\imath}{\mathord}{letters}{7B}
321 \DeclareMathSymbol{\jmath}{\mathord}{letters}{7C}
322 \DeclareMathSymbol{\ell}{\mathord}{letters}{60}
323 \DeclareMathSymbol{\wp}{\mathord}{letters}{7D}
324 \DeclareMathSymbol{\Re}{\mathord}{symbols}{3C}
325 \DeclareMathSymbol{\Im}{\mathord}{symbols}{3D}
326 \DeclareMathSymbol{\partial}{\mathord}{letters}{40}
327 \DeclareMathSymbol{\infty}{\mathord}{symbols}{31}
328 \DeclareMathSymbol{\prime}{\mathord}{symbols}{30}
329 \DeclareMathSymbol{\emptyset}{\mathord}{symbols}{3B}
330 \DeclareMathSymbol{\nabla}{\mathord}{symbols}{72}
331 \DeclareMathSymbol{\top}{\mathord}{symbols}{3E}
332 \DeclareMathSymbol{\bot}{\mathord}{symbols}{3F}
333 \DeclareMathSymbol{\triangle}{\mathord}{symbols}{34}
334 \DeclareMathSymbol{\forall}{\mathord}{symbols}{38}
335 \DeclareMathSymbol{\exists}{\mathord}{symbols}{39}
336 \DeclareMathSymbol{\neg}{\mathord}{symbols}{3A}

```

Alias:

```

337 % \let\not=\neg
338 \DeclareMathSymbol{\not}{\mathord}{symbols}{3A}
339 \DeclareMathSymbol{\flat}{\mathord}{letters}{5B}
340 \DeclareMathSymbol{\natural}{\mathord}{letters}{5C}
341 \DeclareMathSymbol{\sharp}{\mathord}{letters}{5D}

```

```

342 \DeclareMathSymbol{\clubsuit}{\mathord}{symbols}{"7C}
343 \DeclareMathSymbol{\diamondsuit}{\mathord}{symbols}{"7D}
344 \DeclareMathSymbol{\heartsuit}{\mathord}{symbols}{"7E}
345 \DeclareMathSymbol{\spadesuit}{\mathord}{symbols}{"7F}

346 \DeclareRobustCommand\hbar{{\mathchar'26\mkern-9mu}}
347 \DeclareRobustCommand\surd{{\mathchar"1270}}
348 \DeclareRobustCommand\angle{{\vbox{\ialign{$\m@th\scriptstyle##$\crrc
349     \not\mathrel{\mkern14mu}\crrc
350     \noalign{\nointerlineskip}
351     \mkern2.5mu\leaders\hrule \@height.34pt\hfill\mkern2.5mu\crrc}}}}

```

### 6.4.3 Large Operators

```

352 \DeclareMathSymbol{\coprod}{\mathop}{largesymbols}{"60}
353 \DeclareMathSymbol{\bigvee}{\mathop}{largesymbols}{"57}
354 \DeclareMathSymbol{\bigwedge}{\mathop}{largesymbols}{"56}
355 \DeclareMathSymbol{\biguplus}{\mathop}{largesymbols}{"55}
356 \DeclareMathSymbol{\bigcap}{\mathop}{largesymbols}{"54}
357 \DeclareMathSymbol{\bigcup}{\mathop}{largesymbols}{"53}
358 \DeclareMathSymbol{\intop}{\mathop}{largesymbols}{"52}
359 \DeclareRobustCommand\int{\intop\nolimits}
360 \DeclareMathSymbol{\prod}{\mathop}{largesymbols}{"51}
361 \DeclareMathSymbol{\sum}{\mathop}{largesymbols}{"50}
362 \DeclareMathSymbol{\bigotimes}{\mathop}{largesymbols}{"4E}
363 \DeclareMathSymbol{\bigoplus}{\mathop}{largesymbols}{"4C}
364 \DeclareMathSymbol{\bigodot}{\mathop}{largesymbols}{"4A}
365 \DeclareMathSymbol{\ointop}{\mathop}{largesymbols}{"48}
366 \DeclareRobustCommand\oint{\ointop\nolimits}
367 \DeclareMathSymbol{\bigsqcup}{\mathop}{largesymbols}{"46}
368 \DeclareMathSymbol{\smallint}{\mathop}{symbols}{"73}

```

### 6.4.4 Binary symbols

```

369 \DeclareMathSymbol{\triangleleft}{\mathbin}{letters}{"2F}
370 \DeclareMathSymbol{\triangleright}{\mathbin}{letters}{"2E}
371 \DeclareMathSymbol{\bigtriangleup}{\mathbin}{symbols}{"34}
372 \DeclareMathSymbol{\bigtriangledown}{\mathbin}{symbols}{"35}

```

Alias:

```

373 % \let \varbigtriangledown \bigtriangledown
374 % \let \varbigtriangleup \bigtriangleup
375 \DeclareMathSymbol{\varbigtriangleup}{\mathbin}{symbols}{"34}
376 \DeclareMathSymbol{\varbigtriangledown}{\mathbin}{symbols}{"35}

```

These last two synonyms are needed because the `stmaryrd` package redefines them as Operators.

```

377 \DeclareMathSymbol{\wedge}{\mathbin}{symbols}{"5E}
378 \DeclareMathSymbol{\vee}{\mathbin}{symbols}{"5F}

```

Alias:

```

379 % \let \land=\wedge
380 % \let \lor=\vee
381 \DeclareMathSymbol{\land}{\mathbin}{symbols}{"5E}
382 \DeclareMathSymbol{\lor}{\mathbin}{symbols}{"5F}
383 \DeclareMathSymbol{\cap}{\mathbin}{symbols}{"5C}
384 \DeclareMathSymbol{\cup}{\mathbin}{symbols}{"5B}
385 \DeclareMathSymbol{\ddagger}{\mathbin}{symbols}{"7A}

```

```

386 \DeclareMathSymbol{\dagger}{\mathbin}{symbols}{"79}
387 \DeclareMathSymbol{\sqcap}{\mathbin}{symbols}{"75}
388 \DeclareMathSymbol{\sqcup}{\mathbin}{symbols}{"74}
389 \DeclareMathSymbol{\uplus}{\mathbin}{symbols}{"5D}
390 \DeclareMathSymbol{\amalg}{\mathbin}{symbols}{"71}
391 \DeclareMathSymbol{\diamond}{\mathbin}{symbols}{"05}
392 \DeclareMathSymbol{\bullet}{\mathbin}{symbols}{"0F}
393 \DeclareMathSymbol{\wr}{\mathbin}{symbols}{"6F}
394 \DeclareMathSymbol{\div}{\mathbin}{symbols}{"04}
395 \DeclareMathSymbol{\odot}{\mathbin}{symbols}{"0C}
396 \DeclareMathSymbol{\oslash}{\mathbin}{symbols}{"0B}
397 \DeclareMathSymbol{\otimes}{\mathbin}{symbols}{"0A}
398 \DeclareMathSymbol{\ominus}{\mathbin}{symbols}{"09}
399 \DeclareMathSymbol{\oplus}{\mathbin}{symbols}{"08}
400 \DeclareMathSymbol{\mp}{\mathbin}{symbols}{"07}
401 \DeclareMathSymbol{\pm}{\mathbin}{symbols}{"06}
402 \DeclareMathSymbol{\circ}{\mathbin}{symbols}{"0E}
403 \DeclareMathSymbol{\bigcirc}{\mathbin}{symbols}{"0D}
404 \DeclareMathSymbol{\setminus}{\mathbin}{symbols}{"6E}
405 \DeclareMathSymbol{\cdot}{\mathbin}{symbols}{"01}
406 \DeclareMathSymbol{\ast}{\mathbin}{symbols}{"03}
407 \DeclareMathSymbol{\times}{\mathbin}{symbols}{"02}
408 \DeclareMathSymbol{\star}{\mathbin}{letters}{"3F}

```

#### 6.4.5 Relations

```

409 \DeclareMathSymbol{\propto}{\mathrel}{symbols}{"2F}
410 \DeclareMathSymbol{\sqsubseteq}{\mathrel}{symbols}{"76}
411 \DeclareMathSymbol{\sqsupseteq}{\mathrel}{symbols}{"77}
412 \DeclareMathSymbol{\parallel}{\mathrel}{symbols}{"6B}
413 \DeclareMathSymbol{\mid}{\mathrel}{symbols}{"6A}
414 \DeclareMathSymbol{\dashv}{\mathrel}{symbols}{"61}
415 \DeclareMathSymbol{\vdash}{\mathrel}{symbols}{"60}
416 \DeclareMathSymbol{\nearrow}{\mathrel}{symbols}{"25}
417 \DeclareMathSymbol{\searrow}{\mathrel}{symbols}{"26}
418 \DeclareMathSymbol{\nwarrow}{\mathrel}{symbols}{"2D}
419 \DeclareMathSymbol{\swarrow}{\mathrel}{symbols}{"2E}
420 \DeclareMathSymbol{\Leftrightarrow}{\mathrel}{symbols}{"2C}
421 \DeclareMathSymbol{\Leftarrow}{\mathrel}{symbols}{"28}
422 \DeclareMathSymbol{\Rightarrow}{\mathrel}{symbols}{"29}
423 \DeclareRobustCommand\neq{\not=}

```

As `\neq` is robust we should not use `\let` to define `\ne` as then it would change if `\neq` changes.

```

424 \DeclareRobustCommand\ne{\not=}

```

It would ok to use `\let` for those declared by `\DeclareMathSymbol` but for a cleaner interface we avoid it always (just in case the internals change).

```

425 \DeclareMathSymbol{\leq}{\mathrel}{symbols}{"14}
426 \DeclareMathSymbol{\geq}{\mathrel}{symbols}{"15}

```

Alias:

```

427 % \let\le=\leq
428 % \let\ge=\geq
429 \DeclareMathSymbol{\le}{\mathrel}{symbols}{"14}
430 \DeclareMathSymbol{\ge}{\mathrel}{symbols}{"15}

```

```

431 \DeclareMathSymbol{\succ}{\mathrel}{symbols}{"1F}
432 \DeclareMathSymbol{\prec}{\mathrel}{symbols}{"1E}
433 \DeclareMathSymbol{\approx}{\mathrel}{symbols}{"19}
434 \DeclareMathSymbol{\succeq}{\mathrel}{symbols}{"17}
435 \DeclareMathSymbol{\preceq}{\mathrel}{symbols}{"16}
436 \DeclareMathSymbol{\supset}{\mathrel}{symbols}{"1B}
437 \DeclareMathSymbol{\subset}{\mathrel}{symbols}{"1A}
438 \DeclareMathSymbol{\supseteq}{\mathrel}{symbols}{"13}
439 \DeclareMathSymbol{\subseteq}{\mathrel}{symbols}{"12}
440 \DeclareMathSymbol{\in}{\mathrel}{symbols}{"32}
441 \DeclareMathSymbol{\ni}{\mathrel}{symbols}{"33}

```

Alias:

```

442 % \let\owns=\ni
443 \DeclareMathSymbol{\owns}{\mathrel}{symbols}{"33}
444 \DeclareMathSymbol{\gg}{\mathrel}{symbols}{"1D}
445 \DeclareMathSymbol{\ll}{\mathrel}{symbols}{"1C}
446 \DeclareMathSymbol{\not}{\mathrel}{symbols}{"36}
447 \DeclareMathSymbol{\leftrightharpoonup}{\mathrel}{symbols}{"24}
448 \DeclareMathSymbol{\leftarrow}{\mathrel}{symbols}{"20}
449 \DeclareMathSymbol{\rightarrow}{\mathrel}{symbols}{"21}

```

Alias:

```

450 % \let\gets=\leftarrow
451 % \let\to=\rightarrow
452 \DeclareMathSymbol{\gets}{\mathrel}{symbols}{"20}
453 \DeclareMathSymbol{\to}{\mathrel}{symbols}{"21}
454 \DeclareMathSymbol{\mapstochar}{\mathrel}{symbols}{"37}
455 \DeclareRobustCommand\mapsto{\mapstochar\rightarrow}
456 \DeclareMathSymbol{\sim}{\mathrel}{symbols}{"18}
457 \DeclareMathSymbol{\simeq}{\mathrel}{symbols}{"27}
458 \DeclareMathSymbol{\perp}{\mathrel}{symbols}{"3F}
459 \DeclareMathSymbol{\equiv}{\mathrel}{symbols}{"11}
460 \DeclareMathSymbol{\asymp}{\mathrel}{symbols}{"10}
461 \DeclareMathSymbol{\smile}{\mathrel}{letters}{"5E}
462 \DeclareMathSymbol{\frown}{\mathrel}{letters}{"5F}
463 \DeclareMathSymbol{\leftharpoonup}{\mathrel}{letters}{"28}
464 \DeclareMathSymbol{\leftharpoondown}{\mathrel}{letters}{"29}
465 \DeclareMathSymbol{\rightharpoonup}{\mathrel}{letters}{"2A}
466 \DeclareMathSymbol{\rightharpoondown}{\mathrel}{letters}{"2B}

```

Here cometh much profligate robustification of math constructs. Warning: some of these commands may become non-robust if an AMS package is loaded.

Further potential problems: some math font packages may make unfortunate assumptions about some of these definitions that are not true of the robust versions we need.

```

467 \DeclareRobustCommand
468 \cong{\mathrel{\mathpalette\@vereq\sim}} % congruence sign
469 \def\@vereq#1#2{\lower.5p@\vbox{\lineskiplimit\maxdimen\lineskip-.5p@
470 \ialign{${\m@th#1\hfil##\hfil$\crcr#2\crcr=\crcr$}}{}}
471 \DeclareRobustCommand
472 \notin{\mathrel{\m@th\mathpalette\c@ncel\in}}
473 \def\c@ncel#1#2{\m@th\oalign{${\hfil#1\mkern1mu\hfil$\crcr$#1#2$}}
474 \DeclareRobustCommand
475 \rightleftharpoons{\mathrel{\mathpalette\rlh@{}}}

```

```

476 \def\rhlh@#1{\vcenter{\m@th\hbox{\ooalign{\raise2pt
477 \hbox{$#1\rightarrow$}\cr
478 \hbox{$#1\leftarrow$}\cr}}}
479 \DeclareRobustCommand
480 \doteq{\buildrel\textstyle.\over=}

```

#### 6.4.6 Arrows

```

481 \DeclareRobustCommand
482 \joinrel{\mathrel{\mkern-3mu}}
483 \DeclareRobustCommand
484 \relbar{\mathrel{\smash-}} % \smash, because -
485 % has the same height as +

```

In contrast to `plain.tex` `\Relbar` got braces around the equal sign to guard against it being “math active” expanding to `\futurelet...`. This might be the case when packages are implementing shorthands for math, e.g. `=>` meaning `\Rightarrow` etc. It would actually be better not to use `=` in such definitions but instead define something like `\mathequalsign` and use this. However we can’t do this now as it would break other math layouts where characters are in different places (since those wouldn’t know about the need for a new command name).

```

486 \DeclareRobustCommand
487 \Relbar{\mathrel{=}}
488 \DeclareMathSymbol{\lhook}{\mathrel}{letters}{"2C}
489 \DeclareRobustCommand\hookrightarrow{\lhook\joinrel\rightarrow}
490 \DeclareMathSymbol{\rhook}{\mathrel}{letters}{"2D}
491 \DeclareRobustCommand\hookleftarrow{\leftarrow\joinrel\rhook}
492 \DeclareRobustCommand
493 \bowtie{\mathrel{\triangleright}\joinrel\mathrel{\triangleleft}}
494 \DeclareRobustCommand
495 \models{\mathrel{|}\joinrel\Relbar}
496 \DeclareRobustCommand
497 \Longrightarrow{\Relbar\joinrel\rightarrow}

```

LaTeX Change: `\longrightarrow` and `\longleftarrow` redefined to make them robust.

```

498 \DeclareRobustCommand\longrightarrow
499 {\relbar\joinrel\rightarrow}
500 \DeclareRobustCommand\longleftarrow
501 {\leftarrow\joinrel\relbar}
502 \DeclareRobustCommand
503 \Longleftarrow{\Leftarrow\joinrel\Relbar}
504 \DeclareRobustCommand
505 \longmapsto{\mapstochar\longrightarrow}
506 \DeclareRobustCommand
507 \longlefttrightarrow{\leftarrow\joinrel\rightarrow}
508 \DeclareRobustCommand
509 \Longlefttrightarrow{\Leftarrow\joinrel\rightarrow}
510 \DeclareRobustCommand
511 \iff{\;\Longlefttrightarrow\;}

```

#### 6.4.7 Punctuation symbols

```

512 \DeclareMathSymbol{\ldotp}{\mathpunct}{letters}{"3A}
513 \DeclareMathSymbol{\cdotp}{\mathpunct}{symbols}{"01}
514 \DeclareMathSymbol{\colon}{\mathpunct}{operators}{"3A}

```

This is commented out, since `\ldots` is now defined in `ltoutenc.dtx`.

```

515 %\def\@ldots{\mathinner{\ldotp\ldotp\ldotp}}
516 %\DeclareRobustCommand\ldots
517 %      {\relax\ifmmode\@ldots\else\mbox{$\m@th\@ldots$,}\fi}
518 \DeclareRobustCommand
519   \cdots{\mathinner{\cdotp\cdotp\cdotp}}
520 \DeclareRobustCommand
521   \vdots{\vbox{\baselineskip4\p@ \lineskiplimit\z@
522     \kern6\p@\hbox{.}\hbox{.}\hbox{.}}}
523 \DeclareRobustCommand
524   \ddots{\mathinner{\mkern1mu\raise7\p@
525     \vbox{\kern7\p@\hbox{.}}\mkern2mu
526     \raise4\p@\hbox{.}\mkern2mu\raise\p@\hbox{.}\mkern1mu}}

```

#### 6.4.8 Math accents

```

527 \DeclareMathAccent{\acute}{\mathalpha}{operators}{13}
528 \DeclareMathAccent{\grave}{\mathalpha}{operators}{12}
529 \DeclareMathAccent{\ddot}{\mathalpha}{operators}{7F}
530 \DeclareMathAccent{\tilde}{\mathalpha}{operators}{7E}
531 \DeclareMathAccent{\bar}{\mathalpha}{operators}{16}
532 \DeclareMathAccent{\breve}{\mathalpha}{operators}{15}
533 \DeclareMathAccent{\check}{\mathalpha}{operators}{14}
534 \DeclareMathAccent{\hat}{\mathalpha}{operators}{5E}
535 \DeclareMathAccent{\vec}{\mathord}{letters}{7E}
536 \DeclareMathAccent{\dot}{\mathalpha}{operators}{5F}
537 \DeclareMathAccent{\widetilde}{\mathord}{largesymbols}{65}
538 \DeclareMathAccent{\widehat}{\mathord}{largesymbols}{62}

```

For some reason plain T<sub>E</sub>X never bothered to provide a ring accent in math (although it is available in the fonts), but since we got a request for it here we go:

```

539 \DeclareMathAccent{\mathring}{\mathalpha}{operators}{17}

```

#### 6.4.9 Radicals

```

540 \DeclareMathRadical{\sqrtsign}{symbols}{70}{largesymbols}{70}

```

#### 6.4.10 Over and under something, etc

```

541 \DeclareRobustCommand\overrightarrow[1]{\vbox{\m@th\ialign{##\crrc
542   \rightarrowfill\crrc\noalign{\kern-\p@\nointerlineskip}
543   $\hfil\displaystyle{#1}\hfil$\crrc}}}
544 \DeclareRobustCommand\overleftarrow[1]{\vbox{\m@th\ialign{##\crrc
545   \leftarrowfill\crrc\noalign{\kern-\p@\nointerlineskip}%
546   $\hfil\displaystyle{#1}\hfil$\crrc}}}
547 \DeclareRobustCommand\overbrace[1]
548   {\mathop{\vbox{\m@th\ialign{##\crrc\noalign{\kern3\p@}%
549     \downbracefill\crrc\noalign{\kern3\p@\nointerlineskip}%
550     $\hfil\displaystyle{#1}\hfil$\crrc}}}\limits}
551 \DeclareRobustCommand\underbrace[1]{\mathop{\vtop{\m@th\ialign{##\crrc
552   $\hfil\displaystyle{#1}\hfil$\crrc
553   \noalign{\kern3\p@\nointerlineskip}%
554   \upbracefill\crrc\noalign{\kern3\p@}}}\limits}

```

(quite a waste of tokens, IMHO — Frank)

```

555 \DeclareRobustCommand\skew[3]
556   {\{\muskip\z@#1mu\divide\muskip\z@ \tw@ \mkern\muskip\z@
557   #2{\mkern-\muskip\z@#3}\mkern\muskip\z@}\mkern-\muskip\z@}{}}

```

```

558 \DeclareRobustCommand\rightarrowfill{$\m@th\smash-\mkern-7mu%
559 \cleaders\hbox{$\mkern-2mu\smash-\mkern-2mu$}\hfill
560 \mkern-7mu\mathord\rightarrow$}
561 \DeclareRobustCommand\leftarrowfill{$\m@th\mathord\leftarrow\mkern-7mu%
562 \cleaders\hbox{$\mkern-2mu\smash-\mkern-2mu$}\hfill
563 \mkern-7mu\smash-$}
564 \DeclareMathSymbol{\braceld}{\mathord}{largesymbols}{7A}
565 \DeclareMathSymbol{\bracerd}{\mathord}{largesymbols}{7B}
566 \DeclareMathSymbol{\bracelu}{\mathord}{largesymbols}{7C}
567 \DeclareMathSymbol{\braceru}{\mathord}{largesymbols}{7D}
568 \DeclareRobustCommand\downbracefill{$\m@th\setbox\z@\hbox{$\braceld$}%
569 \braceld\leaders\vrule \@height\ht\z@ \@depth\z@\hfill\braceru
570 \bracelu\leaders\vrule \@height\ht\z@ \@depth\z@\hfill\bracerd$}
571 \DeclareRobustCommand\upbracefill{$\m@th\setbox\z@\hbox{$\bracerd$}%
572 \bracelu\leaders\vrule \@height\ht\z@ \@depth\z@\hfill\bracerd
573 \braceld\leaders\vrule \@height\ht\z@ \@depth\z@\hfill\braceru$}

```

#### 6.4.11 Delimiters

```

574 \DeclareMathDelimiter{\lmoustache} % top from (, bottom from )
575 {\mathopen}{largesymbols}{7A}{largesymbols}{40}
576 \DeclareMathDelimiter{\rmoustache} % top from ), bottom from (
577 {\mathclose}{largesymbols}{7B}{largesymbols}{41}
578 \DeclareMathDelimiter{\arrowvert} % arrow without arrowheads
579 {\mathord}{symbols}{6A}{largesymbols}{3C}
580 \DeclareMathDelimiter{\Arrowvert} % double arrow without arrowheads
581 {\mathord}{symbols}{6B}{largesymbols}{3D}
582 \DeclareMathDelimiter{\Vert}
583 {\mathord}{symbols}{6B}{largesymbols}{0D}

```

`\DeclareMathDelimiter` produces a command that is robust (with an internal macro containing the payload) so we should not use `\let` for making an alias

```

584 %\let\|= \Vert
585 \DeclareMathDelimiter{\|}
586 {\mathord}{symbols}{6B}{largesymbols}{0D}
587 \DeclareMathDelimiter{\vert}
588 {\mathord}{symbols}{6A}{largesymbols}{0C}
589 \DeclareMathDelimiter{\uparrow}
590 {\mathrel}{symbols}{22}{largesymbols}{78}
591 \DeclareMathDelimiter{\downarrow}
592 {\mathrel}{symbols}{23}{largesymbols}{79}
593 \DeclareMathDelimiter{\updownarrow}
594 {\mathrel}{symbols}{6C}{largesymbols}{3F}
595 \DeclareMathDelimiter{\Uparrow}
596 {\mathrel}{symbols}{2A}{largesymbols}{7E}
597 \DeclareMathDelimiter{\Downarrow}
598 {\mathrel}{symbols}{2B}{largesymbols}{7F}
599 \DeclareMathDelimiter{\Updownarrow}
600 {\mathrel}{symbols}{6D}{largesymbols}{77}
601 \DeclareMathDelimiter{\backslash} % for double coset G\backslash H
602 {\mathord}{symbols}{6E}{largesymbols}{0F}
603 \DeclareMathDelimiter{\rangle}
604 {\mathclose}{symbols}{69}{largesymbols}{0B}
605 \DeclareMathDelimiter{\langle}
606 {\mathopen}{symbols}{68}{largesymbols}{0A}

```

```

607 \DeclareMathDelimiter{\rbrace
608     {\mathclose}{symbols}{"67}{largesymbols}{"09}
609 \DeclareMathDelimiter{\lbrace
610     {\mathopen}{symbols}{"66}{largesymbols}{"08}
611 \DeclareMathDelimiter{\rceil}
612     {\mathclose}{symbols}{"65}{largesymbols}{"07}
613 \DeclareMathDelimiter{\lceil}
614     {\mathopen}{symbols}{"64}{largesymbols}{"06}
615 \DeclareMathDelimiter{\rfloor}
616     {\mathclose}{symbols}{"63}{largesymbols}{"05}
617 \DeclareMathDelimiter{\lfloor}
618     {\mathopen}{symbols}{"62}{largesymbols}{"04}

```

`\lgroup` `\rgroup` `\bracevert` There are three plain TeX delimiters which are not fully supported by NFSS, since they partly point into a bold cmr font. Allocating a full symbol font, just to have three delimiters seems a bit too much given the limited space available. For this reason only the extensible sizes are supported. If this is not desired one can use, without losing portability, define `\mathbf` and `\mathtt` as font symbol alphabet (setting up `cmr/bx/n` and `cmtt/m/n` as symbol fonts first) and modify the delimiter declarations to point with their small variant to those symbol fonts. (This is done in `oldlfont.dtx` so look there for examples.)

```

619 \DeclareMathDelimiter{\lgroup} % extensible ( with sharper tips
620     {\mathopen}{largesymbols}{"3A}{largesymbols}{"3A}
621 \DeclareMathDelimiter{\rgroup} % extensible ) with sharper tips
622     {\mathclose}{largesymbols}{"3B}{largesymbols}{"3B}
623 \DeclareMathDelimiter{\bracevert} % the vertical bar that extends braces
624     {\mathord}{largesymbols}{"3E}{largesymbols}{"3E}

```

*(End of definition for \lgroup, \rgroup, and \bracevert.)*

## 6.5 Math versions of text commands

The `\mathunderscore` here is really a text definition, so it has been put back into `loutenc.dtx` (by Chris, 30/04/97) and should be removed from here.

These symbols are the math versions of text commands such as `\P`, `\$`, etc.

```

\mathparagraph These math symbols are not in plain TeX.
\mathsection 625 \DeclareMathSymbol{\mathparagraph}{\mathord}{symbols}{"7B}
\mathdollar 626 \DeclareMathSymbol{\mathsection}{\mathord}{symbols}{"78}
\mathsterling 627 \DeclareMathSymbol{\mathdollar}{\mathord}{operators}{"24}
\mathunderscore 628 \DeclareRobustCommand\mathsterling{\mathit{\mathchar"7024}}
629 \DeclareRobustCommand\mathunderscore{\kern.06em\vbox{\hrule\@width.3em}}

```

*(End of definition for \mathparagraph and others.)*

`\mathellipsis` This is plain TeX's `\ldots`.

```

630 \DeclareRobustCommand\mathellipsis{\mathinner{\ldotp\ldotp\ldotp}}%

```

*(End of definition for \mathellipsis.)*

## 6.6 Other special functions and parameters

### 6.6.1 Biggggg

```
631 </math>
632 <*math | latexrelease>
633 <latexrelease>\IncludeInRelease{2018/12/01}%
634 <latexrelease>          {\Big}{Start LR-mode}%
635 \DeclareRobustCommand\big[1]{\leavevmode@ifvmode
636   {\hbox{$\left#1\ vbox to8.5\p@{}\right.\n@space$}}}
637 \DeclareRobustCommand\Big[1]{\leavevmode@ifvmode
638   {\hbox{$\left#1\ vbox to11.5\p@{}\right.\n@space$}}}
639 \DeclareRobustCommand\bigg[1]{\leavevmode@ifvmode
640   {\hbox{$\left#1\ vbox to14.5\p@{}\right.\n@space$}}}
641 \DeclareRobustCommand\Bigg[1]{\leavevmode@ifvmode
642   {\hbox{$\left#1\ vbox to17.5\p@{}\right.\n@space$}}}
643 </math | latexrelease>
644 <latexrelease>\EndIncludeInRelease
645 <latexrelease>\IncludeInRelease{0000/00/00}%
646 <latexrelease>          {\Big}{Start LR-mode}%
647 <latexrelease>\def\big#1{{\hbox{$\left#1\ vbox to8.5\p@{}\right.\n@space$}}}
648 <latexrelease>\def\Big#1{{\hbox{$\left#1\ vbox to11.5\p@{}\right.\n@space$}}}
649 <latexrelease>\def\bigg#1{{\hbox{$\left#1\ vbox to14.5\p@{}\right.\n@space$}}}
650 <latexrelease>\def\Bigg#1{{\hbox{$\left#1\ vbox to17.5\p@{}\right.\n@space$}}}
651 <latexrelease>\EndIncludeInRelease
652 <*math>

653 \def\n@space{\null\delimiterspace\z@ \m@th}
```

### 6.6.2 The log-like functions

`\operator@font` The `\operator@font` determines the symbol font used for log-like functions.

```
654 \def\operator@font{\mathgroup\symoperators}
```

*(End of definition for \operator@font.)*

### 6.6.3 Parameters

```
655 \thinmuskip=3mu
656 \medmuskip=4mu plus 2mu minus 4mu
657 \thickmuskip=5mu plus 5mu
```

This finishes the low-level setup in `fontmath.ltx`.

```
658 </math>
```

## 7 Default cfg files

We provide default `cfg` files here to ensure that on installations that search large file trees we do not pick up some strange customisation files from somewhere.

```
659 <*cfgtext | cfgmath | cfgprel>
660 %%
661 %%
662 %%
663 %% Load the standard setup:
664 %%
665 <+cfgtext>\input{fonttext.ltx}
```

```

666 <+cfgmath>\input{fontmath.ltx}
667 <+cfgprel>\input{preload.ltx}
668 %%
669 %% Small changes could go here; see documentation in cfgguide.tex for
670 %% allowed modifications.
671 %%
672 %% In particular it is not allowed to misuse this configuration file
673 %% to modify internal LaTeX commands!
674 %%
675 %% If you use this file as the basis for configuration please change
676 %% the \ProvidesFile lines to clearly identify your modification, e.g.,
677 %%
678 <+cfgtext>%% \ProvidesFile{fonttext.cfg}[2001/06/01
679 <+cfgmath>%% \ProvidesFile{fonttext.cfg}[2001/06/01
680 <+cfgprel>%% \ProvidesFile{preload.cfg}[2001/06/01
681 %% Customised local font setup]
682 %%
683 %%
684 </cfgtext | cfgmath | cfgprel>

```

## File 31

# preload.dtx

## 1 Overview

This file contains an number of possible settings for preloading fonts during installation of NFSS2 (which is used by L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub>). It will be used to generate the following files:

preload.min	minimal subset of fonts necessary to run NFSS2
preload.ori	preload of CM fonts similar to the old <code>lfonts.tex</code>
preload.ltx	The standard selection of preloads
cmpreload.xpt	preload of CM fonts for 10pt document size
cmpreload.xip	preload of CM fonts for 11pt document size
cmpreload.xii	preload of CM fonts for 12pt document size
dcpreload.xpt	preload of DC fonts for 10pt size
dcpreload.xip	preload of DC fonts for 11pt size
dcpreload.xii	preload of DC fonts for 12pt size

These files are for installations that make use of Computer Modern fonts either old encoding (OT1) or Cork encoding (T1). The Computer Modern fonts with Cork encoding are known as DC-fonts.

Most important is `preload.ltx` which is used during format generation. You are *not* allowed to change this file.

## 2 Customization

You can customize the preloaded fonts in your L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> system by installing a file with the name `preload.cfg`. If this file exists it will be used in place of the system file `preload.ltx`. You can, for example, copy one of the files mentioned above (that can be generated from this source) to `preload.cfg`.

Or you can define completely other preloads. In that case start from `preload.min` since that contains the fonts that have to be preloaded by *\*all\** L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> systems.

Avoid using `preload.ori`, it will load so many fonts that on most installations it is nearly impossible to load other font families afterwards. This file is only generated to show what fonts have been preloaded by L<sup>A</sup>T<sub>E</sub>X 2.09.

If you normally use other fonts than Computer Modern `preload.min` might be best.

**Warning:** If you preload fonts with encodings other than the normally supported encodings you have to declare that encoding in a `fontdef.cfg` configuration file (see the documentation in the file `fontdef.dtx`). Adding an extra encoding to the format might produce non-portable documents, thus this should be avoided if possible.

## 3 Module switches for the DOCSTRIP program

The DOCSTRIP will generate the above file from this source using the following module directives:

driver	produce a documentation driver file
preload	produce a preload... file
cm	for OT1 encoded Computer Modern
dc	for T1 encoded Computer Modern
min	produce minimal subset
xpt	produce 10pt preloads
xipt	produce 11pt preloads
xipt	produce 12pt preloads
ori	produce preloads similar to old <code>lfonts.tex</code>
tex	produce <code>preload.ltx</code>

A typical DOCSTRIP command file would then have entries like:

```
generateFile{preload.min}{t}{\from{preload.dtx}{preload,min}}
```

for generating preload files.

## 4 A driver for this document

The next bit of code contains the documentation driver file for T<sub>E</sub>X, i.e., the file that will produce the documentation you are currently reading. It will be extracted from this file by the DOCSTRIP program.

```

1 <*driver>
2 \documentclass{ltxdoc}
3 %\OnlyDescription % comment out for implementation details
4 \begin{document}
5   \DocInput{preload.dtx}
6 \end{document}
7 </driver>
```

## 5 The code

We begin by loading the math extension font (cmex10) and the L<sup>A</sup>T<sub>E</sub>X line and circle fonts. It is necessary to do this explicitly since these are used by the L<sup>A</sup>T<sub>E</sub>X format. Since the internal font name contains / characters and digits we construct the name via `\csname`. These are the only fonts (!) that must be loaded in this file.

All `\DeclarePreloadSizes` can be removed or others can be added, they only influence the processing speed.

```

8 \expandafter\font\csname OMX/cmex/m/n/10\endcsname=cmex10\relax
9 \font\tenln =line10 \font\tenlnw =linew10\relax
10 \font\tencirc=lcircle10 \font\tencircw=lcirclew10\relax
```

The above fonts should not be touched but anything below this point here in the preload suggestions can be modified without any problems.

```

11 <-tex>%*****
12 <-tex>% Start any modification below this point **
13 <-tex>%*****
14 <-tex>
15 %%
16 %% Computer Modern Roman:
17 %%-----
```

```

# File 32

## lftntcmd.dtx

### Abstract

The commands defined in this file `lftntcmd` are part of the kernel code for  $\text{\LaTeX 2}_{\epsilon}/\text{NFSS2}$ .

It is also meant to serve as documentation for package writers since it demonstrates how to define high-level font changing commands using a small number of creator functions.

## 1 Introduction

Font changes such as `\bfseries`, `\sffamily`, etc. are declarations; this means that their scope is delimited by the grouping structure, either by the next `\end` of some environment or by explicitly using a group, e.g., writing something like `{\bfseries...}` in the source. If you make the mistake of writing `\bfseries{...}` (thinking of `\bfseries` as a command with one argument) then the result is rather striking.

Font declarations are an artifact of the  $\text{\TeX}$  system and for several reasons it is better to avoid them on the user level whenever possible. In  $\text{\LaTeX 3}$  they will probably all be replaced by environments and by font commands taking one argument.

This file defines a creator function for such declarative font switches. This function creates commands which can be used in both math and text.

This file also defines a number of high-level commands (all starting with `\text..`) that have one argument and typeset this argument in the requested way. Thus these commands are for typesetting short pieces of text in a specific family, series or shape. These are all produced as examples of the use of a creator function which is itself also defined in this file.

Table 3 shows all these high-level commands in action. A further advantage of using these commands is that they automatically take care of any necessary italic correction on either side of their argument.

Thus, when using such commands, one does not have to worry about forgetting the italic correction when changing fonts. Only in very few situations is this additional space wrong but, for example, most typographers recommend omitting the italic correction if a small punctuation character, like a comma, directly follows the font change. Since the amount of correction required is partly a matter of taste, you can define in what situations the italic correction should be suppressed. This is done by putting the characters that should cancel a preceding italic correction in the list `\nocorrlist`.<sup>39</sup> The default definition for this list is produced by the following.

```
\newcommand \nocorrlist {,.}
```

It is best to declare the most often used characters first, because this will make the processing slightly faster. For example,

```
\emph{When using the \NFSS{} high-level commands,  
the \emph{proper} use of italic corrections is  
automatically taken care of}. Only
```

---

<sup>39</sup>Any package that changes the `\catcode` of a character inside `\nocorrlist` must then explicitly reset the list. Otherwise the changed character will no longer be recognized by the suppression algorithm.

<i>Command</i>	<i>Corresponds to</i>	<i>Action</i>
<code>\textnormal{..}</code>	<code>\normalfont</code>	Typeset argument in normal family
<code>\textrm{..}</code>	<code>\rmfamily</code>	Typeset argument in roman family
<code>\textsf{..}</code>	<code>\sffamily</code>	Typeset argument in <b>sans serif</b> family
<code>\texttt{..}</code>	<code>\ttfamily</code>	Typeset argument in <b>typewriter</b> family
<code>\textmd{..}</code>	<code>\mdseries</code>	Typeset argument in medium series
<code>\textbf{..}</code>	<code>\bfseries</code>	Typeset argument in <b>bold</b> series
<code>\textup{..}</code>	<code>\upshape</code>	Typeset argument in normal shape
<code>\textit{..}</code>	<code>\itshape</code>	Typeset argument in <i>italic</i> shape
<code>\textsl{..}</code>	<code>\slshape</code>	Typeset argument in <i>slanted</i> shape
<code>\textsc{..}</code>	<code>\scshape</code>	Typeset argument in SMALL CAPS shape
<code>\emph{..}</code>	<code>\em</code>	Typeset argument <i>emphasized</i>

Table 3: Font-change commands with arguments

The font change commands provided here all start with `\text..` to emphasize that they are for use in normal text and to be easily memorable. They automatically take care of any necessary italic correction on either side of the argument.

`\emph{sometimes}` one has to help `\LaTeX{}` by adding a `\verb=\nocorr=` command.

which results in:

*When using the NFSS high-level commands, the proper use of italic corrections is automatically taken care of. Only sometimes one has to help L<sup>A</sup>T<sub>E</sub>X by adding a `\nocorr` command.*

In contrast, the use of the declaration forms is often more appropriate when you define your own commands or environments.

```
\newenvironment{bfitemize}{\begin{itemize}\normalfont\bfseries}
                           {\end{itemize}}
\begin{bfitemize}
\item This environment produces boldface items.
\item It is defined in terms of \LaTeX's
      \texttt{itemize} environment and NFSS
      declarations.
\end{bfitemize}
```

This gives:

- **This environment produces boldface items.**
- **It is defined in terms of L<sup>A</sup>T<sub>E</sub>X's `itemize` environment and NFSS declarations.**

In addition to global customization of when to insert the italic correction, it is of course sometimes necessary to explicitly insert one with `\/`.

It is also possible to suppress the italic correction in individual instances. For this, the command `\nocorr` is provided.

The `\nocorr` must appear as the first or last token inside the braces of the argument of the `\text...` commands, at that end of the text where you wish to suppress the italic correction.

It is worth pointing out here that inserting a `\/` in places where it can have no function (i.e. anywhere except immediately after a slanted letter) is not an error—it will just be silently ignored. Unfortunately this is not true if the redefinition of `\/` in `amstex.sty` is used as this version can cause space to be removed immediately before the `\/`.

## 2 The implementation

`\DeclareTextFontCommand` This is the creator function for `\text..` commands. It gives a warning if `\foo` or `\fragfoo` is already defined.

In math mode it simply puts the font declaration and text into a box (possibly an automagically sized one).

Otherwise it first scans the text to see where `\nocorr` occurs within it. This sets the `\check@ic` commands to do what is necessary concerning the italic correction at both ends.

The algorithm for deciding whether to put in an italic correction is not very subtle: one is added whenever the newly current font is not itself positively sloped, unless the next token is a character in the ‘nocorr’ list. At the end of the text this is done after closing the group so as to check the ‘outer font’. Note that this will often result in adding an italic correction token after a character in an unsloped font; we believe (in early 2003) that this is perhaps inefficient but not dangerous.

It also now checks for empty contents of the text command and optimizes this case. Some care is also taken to check that doing dangerous things in vertical mode is avoided.

The italic correction token is added to the horizontal list before (in the list) an immediately preceding non-zero glob of glue (skip) and any non-zero penalty preceding that since, in the typical case, this puts it immediately after the last character in the preceding word.

Note that it is necessary to put in the `\aftergroup\maybe@ic` at the end of the group so that it comes after any other aftergroup tokens and immediately before the following tokens. It is also necessary to remove the `\fi` from the token list before the group ends; this is done by adding an `\expandafter` just before the closing brace.

```

1  (*2kernel)
2  \def \DeclareTextFontCommand #1#2{%
3    \DeclareRobustCommand#1[1]{%
4      \ifmmode
5        \nfss@text{#2##1}%
6      \else
7        \hmode@bgroup
8        \text@command{##1}%
9        #2\check@icl ##1\check@icr
10       \expandafter
11       \egroup
12       \fi
13           }%
14  }
```

(End of definition for `\DeclareTextFontCommand`.)

`\textrm` Now we define the `\text{family}` commands in terms of the above; `\textttt` does not  
`\textsf` look very nice!  
`\textttt` 15 `\DeclareTextFontCommand{\textrm}{\rmfamily}`  
`\textnormal` 16 `\DeclareTextFontCommand{\textsf}{\sffamily}`  
17 `\DeclareTextFontCommand{\textttt}{\ttfamily}`  
18 `\DeclareTextFontCommand{\textnormal}{\normalfont}`

(End of definition for `\textrm` and others.)

`\textbf` For the series attribute:  
`\textmd` 19 `\DeclareTextFontCommand{\textbf}{\bfseries}`  
20 `\DeclareTextFontCommand{\textmd}{\mdseries}`

(End of definition for `\textbf` and `\textmd`.)

`\textit` And for the shapes:  
`\textsl` 21 `\DeclareTextFontCommand{\textit}{\itshape}`  
`\textsc` 22 `\DeclareTextFontCommand{\textsl}{\slshape}`  
`\textup` 23 `\DeclareTextFontCommand{\textsc}{\scshape}`  
24 `\DeclareTextFontCommand{\textup}{\upshape}`

(End of definition for `\textit` and others.)

`\textulc`  
`\textsw` 25 `</2ekernel>`  
`\textssc` 26 `<*2ekernel | latexrelease>`  
27 `<latexrelease>\IncludeInRelease{2020/02/02}%`  
28 `<latexrelease>{\textulc}{Additional text commands}%`  
29 `\DeclareTextFontCommand{\textulc}{\ulcshape}`  
30 `\DeclareTextFontCommand{\textsw}{\swshape}`  
31 `\DeclareTextFontCommand{\textssc}{\sscshape}`  
32 `</2ekernel | latexrelease>`  
33 `<latexrelease>\EndIncludeInRelease`  
34 `<latexrelease>\IncludeInRelease{0000/00/00}%`  
35 `<latexrelease>{\textulc}{Additional text commands}%`  
36 `<latexrelease>`  
37 `<latexrelease>\let\textulc\@undefined`  
38 `<latexrelease>\let\textsw\@undefined`  
39 `<latexrelease>\let\textssc\@undefined`  
40 `<latexrelease>\EndIncludeInRelease`  
41 `<*2ekernel>`

(End of definition for `\textulc`, `\textsw`, and `\textssc`.)

`\emph` Finally we have the `\em` font change declaration of L<sup>A</sup>T<sub>E</sub>X. The corresponding definition with argument is

42 `\DeclareTextFontCommand{\emph}{\em}`

(End of definition for `\emph`.)

`\nocorr` This is just a label, so it does nothing; it should also be unexpandable.

43 `\let \nocorr \relax`

(End of definition for `\nocorr`.)

`\check@ic1` We define these defaults in case some error causes them to be expanded at the wrong  
`\check@icr` time.

```
44 \let \check@ic1 \@empty
45 \let \check@icr \@empty
```

(End of definition for `\check@ic1` and `\check@icr`.)

`\text@command` This checks for a `\nocorr` as the first token in its argument and also for one in any other  
`\check@nocorr@` position not protected within braces (the latter is treated as if it were at the end of the argument).

Is this the correct action in the ‘empty’ case? It is efficient but typographically it is, strictly, incorrect!

```
46 \def \text@command #1{%
47   \edef \reserved@a {\unexpanded{#1}}%
48   \ifx \reserved@a \@empty
49     \let \check@ic1 \@empty
50     \let \check@icr \@empty
51   \else
```

`\space` is a reserved word in L<sup>A</sup>T<sub>E</sub>X or actually already in plain T<sub>E</sub>X. If somebody really redefines it so many things will break that I don’t see any reason to make this routine here slower than necessary.

```
52 %   \def \reserved@b { }%
53 %   \ifx \reserved@a \reserved@b
54   \ifx \reserved@a \space
55     \let \check@ic1 \@empty
56     \let \check@icr \@empty
57   \else
58     \check@nocorr@ #1\nocorr\@nil
59   \fi
60 \fi
61 }
62 \def \check@nocorr@ #1#2\nocorr#3\@nil {%
```

The two checks are initialised here to their values in the normal case.

```
63 \let \check@ic1 \maybe@ic
64 \def \check@icr {\ifvmode \else \aftergroup \maybe@ic \fi}%
65 \def \reserved@a {\nocorr}%
66 \def \reserved@b {#1}%
67 \def \reserved@c {#3}%
68 \ifx \reserved@a \reserved@b
69   \ifx \reserved@c \@empty
```

In this case there is a `\nocorr` at the start but not at the end, so `\check@ic1` should be empty.

```
70   \let \check@ic1 \@empty
71   \else
```

Otherwise there is a `\nocorr` both at the start and elsewhere, so no italic corrections should be added.

```
72   \let \check@ic1 \@empty
73   \let \check@icr \@empty
74 \fi
```

```

75     \else
76     \ifx \reserved@c \@empty

```

In this case there is no `\nocorr` anywhere, so we need to check for an italic correction at both the beginning and the end. This has been set up as the default so no code is needed here.

```

77     \else

```

In this case there is no `\nocorr` at the start but there is one elsewhere, so no `\aftergroup` is needed.

```

78         \let \check@icr \@empty
79     \fi
80 \fi
81 }

```

*(End of definition for \text@command and \check@nocorr@.)*

`\ifmaybe@ic` Switch used solely within `\maybe@ic` not interfering with other switches.

```

82 \newif\ifmaybe@ic

```

*(End of definition for \ifmaybe@ic.)*

`\maybe@ic` These macros implement the italic correction.

```

\maybe@ic@
83 \def \maybe@ic {\futurelet \@let@token \maybe@ic@}
84 \def \maybe@ic@ {%

```

We first check to see if the current font is positively sloped. (But do not forget the message Rainer sent about an upright font with non-zero slope! Or is this an urban myth?) It has been suggested that this should test against a small positive value, but what?

```

85     \ifdim \fontdimen\@ne\font>\z@
86     \else
87     \maybe@ictrue

```

It would be possible, but probably not worthwhile, to continue the forward scan beyond any closing braces.

```

88     \expandafter \@tfor \expandafter \reserved@a \expandafter : \expandafter =%
89     \nocorrlist

```

We have to hide the `\@let@token` in the macro `\t@st@ic` rather than testing it directly in the loop since it might be `\let` to a `\fi` or `\else`, which would result in chaos.

```

90     \do \t@st@ic

```

Frank thinks that the next bit is inefficient if done after the second change. Chris thinks that most all of this is inefficient for the commonest cases: but that is the price of a cleverer algorithm. It is certainly needed to deal with the use of `\nolinebreak`.

```

91     \ifmaybe@ic \sw@slant \fi
92 \fi
93 }

```

*(End of definition for \maybe@ic and \maybe@ic@.)*

`\t@st@ic` The next token in the input stream is stored in `\@let@token` via a `\let`, the current token from `\nocorrlist` is stored via `\def` in `\reserved@a`. To compare them we have to fiddle around a bit.

If the only things to check were characters then this could be done via an `\if` thus their catcodes would not matter; but this will not work whilst `\futurelet` is used above.

```

94 \def \t@st@ic {%
95   \expandafter\let\expandafter\reserved@b\expandafter=\reserved@a\relax
96   \ifx\reserved@b\@let@token

```

If they are the same we record the fact and jump out of the loop.

```

97     \maybe@icfalse
98     \@break@tfor
99   \fi
100 }

```

*(End of definition for \t@st@ic.)*

`\sw@slant` The definition of the mysterious `\sw@slant` command is as follows.  
`\fix@penalty`

```

101 \def \sw@slant {%

```

It is surely correct to put in an italic correction when there is no skip. If the last thing on the list is actually a zero skip (including things whose dimension part is zero, such as `\hfill`), or anything other than a character, then the italic correction will have no effect.

In order to work correctly with unbreakable spaces from `~` (and other common forms of line-breaking control) we also move back across a penalty before the glue.

```

102   \ifdim \lastskip=\z@
103     \fix@penalty
104   \else
105     \skip@ \lastskip
106     \unskip
107     \fix@penalty
108     \hskip \skip@
109   \fi
110 }

```

The above code means: “If there is a non-zero space just before the current position (`\ifdim...`) save the amount of that space (`\skip@\lastskip`), remove it (`\unskip`), then do a similar thing if there is a penalty just before the skip, and finally put the space back in.”

Since zero glue cannot be distinguished in this context from no glue, we dare not put in an `\hskip` in this case as this may produce an unwanted breakpoint. This is not satisfactory.

The penalty before the glue is handled similarly, with the same caveats concerning the zero case. Is this the first recorded use of `\unpenalty` in standard L<sup>A</sup>T<sub>E</sub>X code?

```

111 \def \fix@penalty {%
112   \ifnum \lastpenalty=\z@
113     @@italiccorr
114   \else
115     \count@ \lastpenalty
116     \unpenalty
117     @@italiccorr

```

```

118     \penalty \count@
119     \fi
120 }

```

(End of definition for `\sw@slant` and `\fix@penalty`.)

**\nocorrlist** This holds the list of characters that should prevent italic correction. They should be ordered by decreasing frequency of use. If any such character is made active later on one needs to redefine the list so that the active character becomes part of it.

```

121 \def \nocorrlist {,.}

```

(End of definition for `\nocorrlist`.)

**\nfss@text** This command will by default behave like a L<sup>A</sup>T<sub>E</sub>X `\mbox` but may be redefined by packages such as `amstext.sty` to be a bit cleverer.

```

122 \ifx \nfss@text\undefined
123   \def \nfss@text {\leavevmode\hbox}
124 \fi

```

(End of definition for `\nfss@text`.)

**\DeclareOldFontCommand** This is the function used to create declarative font-changing commands that can also be used to change alphabets in math-mode.

Usage: `\DeclareOldFontCommand \fn{<font-change decls>} <math-alphabet>`

Here `\fn` is the font-declaration command being defined, `<font-change decls>` is the declaration it will expand to in text-mode, and `<math-alphabet>` is the (single) math alphabet specifier which is to be used in math-mode.

It does not care whether the command being defined already exists but it does give a warning if it redefines anything.

Here are some typical examples of its use in conjunction with more basic NFSS2 font commands.

```

\DeclareOldFontCommand{\rm}{\normalfont\rmfamily}{\mathrm}
\DeclareOldFontCommand{\sf}{\normalfont\sffamily}{\mathsf}
\DeclareOldFontCommand{\tt}{\normalfont\ttfamily}{\mathtt}

```

```

125 \def \DeclareOldFontCommand #1#2#3{%
126   \DeclareRobustCommand #1{\@fontswitch {#2}{#3}}%
127 }

```

(End of definition for `\DeclareOldFontCommand`.)

**\@fontswitch** **\@math@egroup** These two commands actually do the necessary tests and declarative font- or alphabet-changing.

```

\@math@egroup
\@math@egroup
128 \def \@fontswitch #1#2{%
129   \ifmmode
130     \let \math@bgroup \relax
131     \def \math@egroup {\let \math@bgroup \@math@bgroup
132                       \let \math@egroup \@math@egroup}%

```

We need to have a `\relax` in the following line in case the `#2` is something like `\mathsf` grabbing the next token as an argument. For this reason the code also uses explicit arguments again (see pr/1275).

```

133     #2\relax
134   \else
135     #1%
136   \fi
137 }
138 \let \@@math@bgroup \math@bgroup
139 \let \@@math@egroup \math@egroup

(End of definition for \@fontswitch, \@@math@egroup, and \@@math@egroup.)

These commands are available only in the preamble.

140 \@onlypreamble \DeclareTextFontCommand
141 \@onlypreamble \DeclareOldFontCommand

```

### 3 Initialization

```

\normalsize This is defined to produce an error.

142 \def\normalsize{%
143   \@latex@error {The font size command \protect\normalsize\space
144                 is not defined:\MessageBreak
145                 there is probably something wrong with
146                 the class file}\@eha
147 }
148 \</2ekernel>

(End of definition for \normalsize.)

```

## File 33

# ltxtextcomp.dtx

This file contains the implementation for accessing the glyphs provided by the TS1 encoding (Text Companion Encoding). This is now offered as part of the kernel and so the `textcomp` package which used to provide the definitions is now mainly needed for compatibility reasons (and doesn't do much any more).

```
1 <*2ekernel | latexrelease>
2 <latexrelease>\NewModuleRelease{2020/02/02}{ltxtextcomp}
3 <latexrelease>                                {Text Companion symbols}
```

`\oldstylenums`  
`\legacyoldstylenums`

Preserve the old definition of `\oldstylenums` under a different name.

This macro implements old style numerals but only works if we assume that the standard math fonts are used. Thus it needs changing in case other math encodings are used.

```
4 \DeclareRobustCommand\legacyoldstylenums[1]{%
5   \begingroup
```

Provide spacing using the interword space of the current font.

```
6   \spaceskip\fontdimen\tw@\font
```

Then switch to the math italic font. We don't change the current value of `\f@series` which means that you can use bold numerals if `\bfseries` is in force. As family we use `\rmdefault` which means that this only works if there exist an OML encoded version of that font or rather a corresponding .fd file (which is the case for standard L<sup>A</sup>T<sub>E</sub>X fonts even though they only contain substitutions).

```
7   \usefont{OML}{\rmdefault}{\f@series}{it}%
8   \mathgroup\symletters #1%
9   \endgroup
10 }
```

And here is the improved one that adjusts depending on surroundings.

```
11 \DeclareRobustCommand\oldstylenums[1]{%
12   \begingroup
13   \ifmmode
14     \mathgroup\symletters #1%
15   \else
```

The `\CheckEncodingSubset` is discussed below.

```
16   \CheckEncodingSubset\@use@text@encoding{TS1}{\tc@oldstylesubst2{{#1}}}%
17   \fi
18   \endgroup
19 }
```

The helper to select the substitution if needed.

```
20 \def\tc@oldstylesubst#1{%
21   \tc@errorwarn
22     {Oldstyle digits unavailable for
23     family \f@family.\MessageBreak
24     Default oldstyle digits used instead}\@eha
25   \bgroup
26   \expand@font@defaults
```

The substitution defaults are provided in the file `fonttext.ltx`.

```

27     \ifx\f@family\rmdef@ult
28         \fontfamily\rmsubstdefault
29     \else\ifx\f@family\sfddef@ult
30         \fontfamily\sfsbstdefault
31     \else\ifx\f@family\ttdef@ult
32         \fontfamily\ttsbstdefault
33     \else
34         \fontfamily\textcompsubstdefault
35     \fi\fi\fi
36     \fontencoding{TS1}\selectfont#1%
37 \egroup
38 }

```

*(End of definition for \oldstylenums and \legacyoldstylenums.)*

`\textcompsubstdefault` Here is the default for the “unknown” case:

```

39 \def\textcompsubstdefault{\rmsubstdefault}

```

*(End of definition for \textcompsubstdefault.)*

To set up the glyphs for the subsets we need a number helpers.

`\tc@errorwarn` To we produce errors, warnings, or only info in the transcripts if glyphs require substitutions? By default it is “info” only. With the `textcomp` package that can be changed.

```

40 \def\tc@errorwarn#1#2{\@latex@info{#1}}

```

*(End of definition for \tc@errorwarn.)*

`\tc@subst`

```

41 \def\tc@subst#1{%
42     \tc@errorwarn
43     {Symbol \string#1 not provided by\MessageBreak
44     font family \f@family\space
45     in TS1 encoding.\MessageBreak Default family used instead}\@eha
46 \bgroup
47     \expand@font@defaults
48     \ifx\f@family\rmdef@ult
49         \fontfamily\rmsubstdefault
50     \else\ifx\f@family\sfddef@ult
51         \fontfamily\sfsbstdefault
52     \else\ifx\f@family\ttdef@ult
53         \fontfamily\ttsbstdefault
54     \else
55         \fontfamily\textcompsubstdefault
56     \fi\fi\fi

```

Whatever default was chosen, we claim now (locally hopefully) that it can handle all slots (even if not true) to avoid looping in certain situations, e.g., when something was set up incorrectly.

```

57     \@namedef{TS1:\f@family}{0}%
58     \selectfont#1%
59 \egroup
60 }

```

*(End of definition for \tc@subst.)*

`\tc@fake@euro` `\tc@fake@euro` is an example of a “fake” definition to use in arg #3 of the command `\CheckEncodingSubset` when a symbol is not available in a certain font family. Here we produce a poor man’s Euro symbol by combining a “C” with a “=”.

```

61 \def\tc@fake@euro#1{%
62   \leavevmode
63   \@font@info{Faking \noexpand#1for font family
64               \f@family\MessageBreak in TS1 encoding}%
65   \valign{##\cr
66     \vfil\hbox to 0.07em{\dimen@\f@size\p@
67                           \math@fontsfalse
68                           \fontsize{.7\dimen@}\z@\selectfont=\hss}%
69     \vfil\cr%
70     \hbox{C}\crrcr
71   }%
72 }

```

*(End of definition for \tc@fake@euro.)*

`\tc@check@symbol` These are two abbreviations that we use below to check symbols and accents in TS1.  
`\tc@check@accent` Only there to save some space, e.g., we can then write

```
DeclareTextCommandDefault{\textcurrency}{\tc@check@symbol3\textcurrency}
```

to ensure that `\textcurrency` is only typeset if the current font has a TS1 subset id of less than 3. Otherwise `\tc@error` is called telling the user that for this font family `\textcurrency` is not available.

```
73 \def\tc@check@symbol{\CheckEncodingSubset\UseTextSymbol{TS1}\tc@subst}
```

Accents have been made an error in the `textcomp` package when not available. Now that we provide the functionality in the kernel we avoid the error by swapping in a T1 accent if the TS1 accent is not available.

```

74 %\def\tc@check@accent{\CheckEncodingSubset\UseTextAccent{TS1}\tc@error}
75 \def\tc@check@accent#1{\CheckEncodingSubset\UseTextAccent
76                           {TS1}{\tc@swap@accent#1}}
77 \def\tc@swap@accent#1#2{\UseTextAccent{T1}#1}

```

*(End of definition for \tc@check@symbol and \tc@check@accent.)*

## 1 Sub-encodings

Here are the default definitions for the TS1 symbols. First those that we assume are always available if a font implements TS1.

```

78 \DeclareTextSymbolDefault{\textdollar}{TS1}
79 \UndeclareTextCommand{\textdollar}{OT1} % don't use the OT1 def any longer
80 \DeclareTextSymbolDefault{\textsterling}{TS1}
81 \UndeclareTextCommand{\textsterling}{OT1}% don't use the OT1 def any longer
82 \DeclareTextSymbolDefault{\textperthousand}{TS1}
83 \UndeclareTextCommand{\textperthousand}{T1} % don't use the T1 def

```

Using `\UndeclareTextCommand` above is enough only if the encoding definition files are not reloaded afterwards. In the past that happened if `fontenc` was used in the document preamble (not any longer). So in some sense it is better to fully remove them from the encoding files, but for rollbacks it is easier to keep them in for now.

These are the standard `itemize` and footnote symbols originally taken from OMS and now from TS1:

```
84 \DeclareTextSymbolDefault{\textasteriskcentered}{TS1}
85 \DeclareTextSymbolDefault{\textbullet}{TS1}
86 \DeclareTextSymbolDefault{\textdaggerdbl}{TS1}
87 \DeclareTextSymbolDefault{\textdagger}{TS1}
88 \DeclareTextSymbolDefault{\textparagraph}{TS1}
89 \DeclareTextSymbolDefault{\textperiodcentered}{TS1}
90 \DeclareTextSymbolDefault{\textsection}{TS1}
```

And here are the other TS1 glyphs that are implemented by every font (or nearly every)—a few are commented out and moved to sub-encoding 9, because they aren't around in some fonts.

```
91 %%\DeclareTextSymbolDefault{\textbardbl}{TS1} % subst in sub-enc 9 above
92 \DeclareTextSymbolDefault{\textbrokenbar}{TS1}
93 %%\DeclareTextSymbolDefault{\textcelsius}{TS1} % subst in sub-enc 9 above
94 \DeclareTextSymbolDefault{\textcent}{TS1}
95 \DeclareTextSymbolDefault{\textcopyright}{TS1}
96 \DeclareTextSymbolDefault{\textdegree}{TS1}
97 \DeclareTextSymbolDefault{\textdiv}{TS1}
98 \DeclareTextSymbolDefault{\textlnot}{TS1}
99 \DeclareTextSymbolDefault{\textonehalf}{TS1}
100 \DeclareTextSymbolDefault{\textonequarter}{TS1}
101 %%\DeclareTextSymbolDefault{\textonesuperior}{TS1} % subst in sub-enc 9 above
102 \DeclareTextSymbolDefault{\textordfeminine}{TS1}
103 \DeclareTextSymbolDefault{\textordmasculine}{TS1}
104 \DeclareTextSymbolDefault{\textpm}{TS1}
105 \DeclareTextSymbolDefault{\textquotesingle}{TS1}
106 \DeclareTextSymbolDefault{\textquotestraightbase}{TS1}
107 \DeclareTextSymbolDefault{\textquotestraightdblbase}{TS1}
108 \DeclareTextSymbolDefault{\textregistered}{TS1}
109 %%\DeclareTextSymbolDefault{\textthreequartersemdash}{TS1} % subst in sub-enc 9 above
110 \DeclareTextSymbolDefault{\textthreequarters}{TS1}
111 %%\DeclareTextSymbolDefault{\textthreesuperior}{TS1} % subst in sub-enc 9 above
112 \DeclareTextSymbolDefault{\texttimes}{TS1}
113 \DeclareTextSymbolDefault{\texttrademark}{TS1}
114 %%\DeclareTextSymbolDefault{\texttwelveudash}{TS1} % subst in sub-enc 9 above
115 %%\DeclareTextSymbolDefault{\texttwosuperior}{TS1} % subst in sub-enc 9 above
116 \DeclareTextSymbolDefault{\textyen}{TS1}

117 \DeclareTextSymbolDefault{\textcapitalcompwordmark}{TS1}
118 \DeclareTextSymbolDefault{\textascendercompwordmark}{TS1}
```

In the following sections the remaining default definitions are ordered by sub-encoding in which they are become **unavailable**, i.e., they are not provided in the sub-encoding with that number and all sub-encodings with higher numbers.

Thus the symbols that are available in sub-encoding  $x$  are the symbols above (always available) and the symbols listed as becoming unavailable in sub-encodings  $x + 1$  and higher.

## 1.1 Unavailable in sub-encoding 1 and higher (drop symbols not working in Latin Modern)

The `\textcircled` is available but the glyph is simply too small so we keep using the OMS glyph.

```
119 \DeclareTextCommandDefault{\textcircled}
120   {\CheckEncodingSubset\UseTextAccent{TS1}{\UseTextAccent{OMS}}1\textcircled}
```

## 1.2 Unavailable in sub-encoding 2 (majority of new OTF fonts via autost) and higher

```
121 \DeclareTextCommandDefault{\t}
122   {\CheckEncodingSubset\UseTextAccent{TS1}{\UseTextAccent{OML}}2\t}
```

Capital accents are really only very seldom implemented, so from sub-encoding 2 onwards we use the normal T1 accents if they are asked for in the document.

In Unicode engines we don't implement them at all but always use the basic accents instead. whether that works or not really depends on the font, something like `\"X` usually comes out wrong in Unicode engines.

```
123 \ifx\Umathcode\@undefined
124   \DeclareTextCommandDefault{\capitalacute}
125     {\tc@check@accent{\'}2\capitalacute}
126   \DeclareTextCommandDefault{\capitalbreve}
127     {\tc@check@accent{\u}2\capitalbreve}
128   \DeclareTextCommandDefault{\capitalcaron}
129     {\tc@check@accent{\v}2\capitalcaron}
130   \DeclareTextCommandDefault{\capitalcedilla}
131     {\tc@check@accent{\c}2\capitalcedilla}
132   \DeclareTextCommandDefault{\capitalcircumflex}
133     {\tc@check@accent{\^}2\capitalcircumflex}
134   \DeclareTextCommandDefault{\capitaldieresis}
135     {\tc@check@accent{\"}2\capitaldieresis}
136   \DeclareTextCommandDefault{\capitaldotaccent}
137     {\tc@check@accent{\.}2\capitaldotaccent}
138   \DeclareTextCommandDefault{\capitalgrave}
139     {\tc@check@accent{\`}2\capitalgrave}
140   \DeclareTextCommandDefault{\capitalhungarumlaut}
141     {\tc@check@accent{\H}2\capitalhungarumlaut}
142   \DeclareTextCommandDefault{\capitalmacron}
143     {\tc@check@accent{\=}2\capitalmacron}
144   \DeclareTextCommandDefault{\capitalogonek}
145     {\tc@check@accent{\k}2\capitalogonek}
146   \DeclareTextCommandDefault{\capitalring}
147     {\tc@check@accent{\r}2\capitalring}
148   \DeclareTextCommandDefault{\capitaltie}
149     {\tc@check@accent{\t}2\capitaltie}
150   \DeclareTextCommandDefault{\capitaltilde}
151     {\tc@check@accent{\~}2\capitaltilde}
```

For `\newtie` and `\capitalnewtie` this is actually wrong, they should pick up the accent from the substitution font (not done yet).

```
152   \DeclareTextCommandDefault{\newtie}
153     {\tc@check@accent{\t}2\newtie}
154   \DeclareTextCommandDefault{\capitalnewtie}
```

```
155             {\tc@check@accent{\t}2\capitalnewtie}
```

In Unicode engines we just execute the simple accents:

```
156 \else
157   \DeclareTextCommandDefault\capitalacute{\@tabacckludge'}
158   \DeclareTextCommandDefault\capitalbreve{\u}
159   \DeclareTextCommandDefault\capitalcaron{\v}
160   \DeclareTextCommandDefault\capitalcedilla{\c}
161   \DeclareTextCommandDefault\capitalcircumflex{\^}
162   \DeclareTextCommandDefault\capitaldieresis{"}
163   \DeclareTextCommandDefault\capitaldotaccent{.}
164   \DeclareTextCommandDefault\capitalgrave{\@tabacckludge`}
165   \DeclareTextCommandDefault\capitalhungarumlaut{\H}
166   \DeclareTextCommandDefault\capitalmacron{\@tabacckludge=}
167   \DeclareTextCommandDefault\capitalnewtie{\t}
168   \DeclareTextCommandDefault\capitalogonek{\k}
169   \DeclareTextCommandDefault\capitalring{\r}
170   \DeclareTextCommandDefault\capitaltie{\t}
171   \DeclareTextCommandDefault\capitaltilde{\~}
172   \DeclareTextCommandDefault\newtie{\t}
173 \fi
```

The next two symbols exist in some fonts (faked?), but we ignore that to keep the subsets reasonable compact and most important linear.

```
174 \DeclareTextCommandDefault{\textlbrackdbl}
175             {\tc@check@symbol2\textlbrackdbl}
176 \DeclareTextCommandDefault{\textrbrackdbl}
177             {\tc@check@symbol2\textrbrackdbl}
```

Old style numerals are again in some fonts but using -OsF, etc. is the better approach to get them, so we claim they aren't in sub-encoding 2 as that's true for most fonts.

```
178 \DeclareTextCommandDefault{\texteightoldstyle}
179             {\tc@check@symbol2\texteightoldstyle}
180 \DeclareTextCommandDefault{\textfiveoldstyle}
181             {\tc@check@symbol2\textfiveoldstyle}
182 \DeclareTextCommandDefault{\textfouroldstyle}
183             {\tc@check@symbol2\textfouroldstyle}
184 \DeclareTextCommandDefault{\textnineoldstyle}
185             {\tc@check@symbol2\textnineoldstyle}
186 \DeclareTextCommandDefault{\textoneoldstyle}
187             {\tc@check@symbol2\textoneoldstyle}
188 \DeclareTextCommandDefault{\textsevenoldstyle}
189             {\tc@check@symbol2\textsevenoldstyle}
190 \DeclareTextCommandDefault{\textsixoldstyle}
191             {\tc@check@symbol2\textsixoldstyle}
192 \DeclareTextCommandDefault{\textthreeoldstyle}
193             {\tc@check@symbol2\textthreeoldstyle}
194 \DeclareTextCommandDefault{\texttwooldstyle}
195             {\tc@check@symbol2\texttwooldstyle}
196 \DeclareTextCommandDefault{\textzerooldstyle}
197             {\tc@check@symbol2\textzerooldstyle}
```

The next set of glyphs is special to T<sub>E</sub>X fonts (and available with a few older PS fonts supported through virtual fonts), but not any longer in the majority of fonts provided through autost, so we pretend there aren't available in sub-encoding 2 and below.

```
198 \DeclareTextCommandDefault{\textacutedbl}
```

```

199             {\tc@check@symbol2\textacutedbl}
200 \DeclareTextCommandDefault{\textasciiacute}
201             {\tc@check@symbol2\textasciiacute}
202 \DeclareTextCommandDefault{\textasciibreve}
203             {\tc@check@symbol2\textasciibreve}
204 \DeclareTextCommandDefault{\textasciicaron}
205             {\tc@check@symbol2\textasciicaron}
206 \DeclareTextCommandDefault{\textasciidieresis}
207             {\tc@check@symbol2\textasciidieresis}
208 \DeclareTextCommandDefault{\textasciigrave}
209             {\tc@check@symbol2\textasciigrave}
210 \DeclareTextCommandDefault{\textasciimacron}
211             {\tc@check@symbol2\textasciimacron}
212 \DeclareTextCommandDefault{\textgravedbl}
213             {\tc@check@symbol2\textgravedbl}
214 \DeclareTextCommandDefault{\texttildelow}
215             {\tc@check@symbol2\texttildelow}

```

Finally those below are only available in CM-based fonts but in no font that has its origin outside of the T<sub>E</sub>X world.

```

216 \DeclareTextCommandDefault{\textbaht}
217             {\tc@check@symbol2\textbaht}
218 \DeclareTextCommandDefault{\textbigcircle}
219             {\tc@check@symbol2\textbigcircle}
220 \DeclareTextCommandDefault{\textborn}
221             {\tc@check@symbol2\textborn}
222 \DeclareTextCommandDefault{\textcentoldstyle}
223             {\tc@check@symbol2\textcentoldstyle}
224 \DeclareTextCommandDefault{\textcircledP}
225             {\tc@check@symbol2\textcircledP}
226 \DeclareTextCommandDefault{\textcopyleft}
227             {\tc@check@symbol2\textcopyleft}
228 \DeclareTextCommandDefault{\textdblhyphenchar}
229             {\tc@check@symbol2\textdblhyphenchar}
230 \DeclareTextCommandDefault{\textdblhyphen}
231             {\tc@check@symbol2\textdblhyphen}
232 \DeclareTextCommandDefault{\textdied}
233             {\tc@check@symbol2\textdied}
234 \DeclareTextCommandDefault{\textdiscount}
235             {\tc@check@symbol2\textdiscount}
236 \DeclareTextCommandDefault{\textdivorced}
237             {\tc@check@symbol2\textdivorced}
238 \DeclareTextCommandDefault{\textdollaroldstyle}
239             {\tc@check@symbol2\textdollaroldstyle}
240 \DeclareTextCommandDefault{\textguarani}
241             {\tc@check@symbol2\textguarani}
242 \DeclareTextCommandDefault{\textleaf}
243             {\tc@check@symbol2\textleaf}
244 \DeclareTextCommandDefault{\textlquill}
245             {\tc@check@symbol2\textlquill}
246 \DeclareTextCommandDefault{\textmarried}
247             {\tc@check@symbol2\textmarried}
248 \DeclareTextCommandDefault{\textmho}
249             {\tc@check@symbol2\textmho}
250 \DeclareTextCommandDefault{\textmusicalnote}

```

```

251             {\tc@check@symbol2\textmusicalnote}
252 \DeclareTextCommandDefault{\textnaira}
253             {\tc@check@symbol2\textnaira}
254 \DeclareTextCommandDefault{\textopenbullet}
255             {\tc@check@symbol2\textopenbullet}
256 \DeclareTextCommandDefault{\textpeso}
257             {\tc@check@symbol2\textpeso}
258 \DeclareTextCommandDefault{\textpilcrow}
259             {\tc@check@symbol2\textpilcrow}
260 \DeclareTextCommandDefault{\textrecipe}
261             {\tc@check@symbol2\textrecipe}
262 \DeclareTextCommandDefault{\textreferencemark}
263             {\tc@check@symbol2\textreferencemark}
264 \DeclareTextCommandDefault{\textrquill}
265             {\tc@check@symbol2\textrquill}
266 \DeclareTextCommandDefault{\textservicemark}
267             {\tc@check@symbol2\textservicemark}
268 \DeclareTextCommandDefault{\textsurd}
269             {\tc@check@symbol2\textsurd}

```

The `\textpertenthousand` also belongs in this group but here we have a choice: in T1 there is a definition for `\textpertenthousand` making the symbol up from % and `\char 24` (twice) but in many fonts that char doesn't exist and the slot is reused for random ligatures. So better not use it because often it is wrong. But pointing to TS1 is also not great as only a few fonts have it as a real symbol, so we get a substitution to CM or LM.

Alternatively we could just state that the symbol is unavailable in those fonts. For now I substitute.

```

270 \DeclareTextCommandDefault{\textpertenthousand}
271             {\tc@check@symbol2\textpertenthousand}
272 \UndeclareTextCommand{\textpertenthousand}{T1}

```

### 1.3 Unavailable in sub-encoding 3 and higher

Sub-encoding 2 is the one where we lose many symbols. In the higher-numbered sub-encodings we see only a few dropped additionally.

```

273 \DeclareTextCommandDefault{\textlangle}
274             {\tc@check@symbol3\textlangle}
275 \DeclareTextCommandDefault{\textrangle}
276             {\tc@check@symbol3\textrangle}

```

### 1.4 Unavailable in sub-encoding 4 and higher

```

277 \DeclareTextCommandDefault{\textcolonmonetary}
278             {\tc@check@symbol4\textcolonmonetary}
279 \DeclareTextCommandDefault{\textdong}
280             {\tc@check@symbol4\textdong}
281 \DeclareTextCommandDefault{\textdownarrow}
282             {\tc@check@symbol4\textdownarrow}
283 \DeclareTextCommandDefault{\textleftarrow}
284             {\tc@check@symbol4\textleftarrow}
285 \DeclareTextCommandDefault{\textlira}
286             {\tc@check@symbol4\textlira}
287 \DeclareTextCommandDefault{\textrightarrow}

```

```

288             {\tc@check@symbol4\textrightarrow}
289 \DeclareTextCommandDefault{\textuparrow}
290             {\tc@check@symbol4\textuparrow}
291 \DeclareTextCommandDefault{\textwon}
292             {\tc@check@symbol4\textwon}

```

## 1.5 Unavailable in sub-encoding 5 (most older PS fonts) and higher

Most older PS fonts (supported in T<sub>E</sub>X since the early nineties when virtual fonts became available) are sorted under this sub-encoding. But in reality, many of them don't have all glyphs that should be available in sub-encoding 5. Instead they show little squares, i.e., they produce “tofu” if you are unlucky.

But the coverage is so random that it is impossible to sort them properly and if we tried to ensure that they only typeset those glyphs that are really always available, we would have to put them all into sub-encoding 9; so putting them into 5 is really a compromise.

Modern fonts usually don't typeset a tofu character if a glyph is missing. They are therefore only classified as sub-encoding 5 if they really support its glyph set completely.

```

293 \DeclareTextCommandDefault{\textestimated}
294             {\tc@check@symbol5\textestimated}
295 \DeclareTextCommandDefault{\textnumero}
296             {\tc@check@symbol5\textnumero}

```

## 1.6 Unavailable in sub-encoding 6 and higher

```

297 \DeclareTextCommandDefault{\textflorin}
298             {\tc@check@symbol6\textflorin}
299 \DeclareTextCommandDefault{\textcurrency}
300             {\tc@check@symbol6\textcurrency}

```

## 1.7 Unavailable in sub-encoding 7 and higher

```

301 \DeclareTextCommandDefault{\textfractionsolidus}
302             {\tc@check@symbol7\textfractionsolidus}
303 \DeclareTextCommandDefault{\textohm}
304             {\tc@check@symbol7\textohm}
305 \DeclareTextCommandDefault{\textmu}
306             {\tc@check@symbol7\textmu}
307 \DeclareTextCommandDefault{\textminus}
308             {\tc@check@symbol7\textminus}

```

## 1.8 Unavailable in sub-encoding 8 and higher

```

309 \DeclareTextCommandDefault{\textblank}
310             {\tc@check@symbol{8}\textblank}
311 \DeclareTextCommandDefault{\textinterrobangdown}
312             {\tc@check@symbol{8}\textinterrobangdown}
313 \DeclareTextCommandDefault{\textinterrobang}
314             {\tc@check@symbol{8}\textinterrobang}

```

Fonts with this sub-encoding don't have a Euro symbol, but instead of substituting we fake it.

```

315 \DeclareTextCommandDefault{\texteuro}
316     {\CheckEncodingSubset\UseTextSymbol{TS1}\tc@fake@euro{8}\texteuro}

```

## 1.9 Unavailable in Sub-encoding 9 (most missing)

```
317 \DeclareTextCommandDefault{\textcelsius}
318         {\tc@check@symbol{9}\textcelsius}
319 \DeclareTextCommandDefault{\textonesuperior}
320         {\tc@check@symbol{9}\textonesuperior}
321 \DeclareTextCommandDefault{\textthreequartersemdash}
322         {\tc@check@symbol{9}\textthreequartersemdash}
323 \DeclareTextCommandDefault{\textthreesuperior}
324         {\tc@check@symbol{9}\textthreesuperior}
325 \DeclareTextCommandDefault{\texttwelveudash}
326         {\tc@check@symbol{9}\texttwelveudash}
327 \DeclareTextCommandDefault{\texttwosuperior}
328         {\tc@check@symbol{9}\texttwosuperior}
329 \DeclareTextCommandDefault{\textbardbl}
330         {\tc@check@symbol{9}\textbardbl}
```

## 2 Unicode engine specials

If we are using a unicode engine we handle some glyphs differently, so this here are the definitions for the Unicode encoding (overwriting the defaults above).

```
331 \ifx \Umathcode\@undefined \else
```

This set should be taken from TS1 encoding even if it means you get it from the default font for that encoding.

```
332 %\DeclareTextSymbol{\textcopyright}{TS1}{171}
333 %\DeclareTextSymbol{\textdblhyphen}{TS1}{45}
334 %\DeclareTextSymbol{\textdblhyphenchar}{TS1}{127}
335 %\DeclareTextSymbol{\textquotestraightbase}{TS1}{13}
336 %\DeclareTextSymbol{\textquotestraightdblbase}{TS1}{18}
337 %\DeclareTextSymbol{\textleaf}{TS1}{108}
338 %\DeclareTextSymbol{\texttwelveudash}{TS1}{21}
339 %\DeclareTextSymbol{\textthreequartersemdash}{TS1}{22}
```

If oldstyle numerals are asked for we just use \oldstylenums.

```
340 \DeclareTextCommand{\textzerooldstyle} \UnicodeEncodingName{\oldstylenums{0}}
341 \DeclareTextCommand{\textoneoldstyle} \UnicodeEncodingName{\oldstylenums{1}}
342 \DeclareTextCommand{\texttwooldstyle} \UnicodeEncodingName{\oldstylenums{2}}
343 \DeclareTextCommand{\textthreeoldstyle} \UnicodeEncodingName{\oldstylenums{3}}
344 \DeclareTextCommand{\textfouroldstyle} \UnicodeEncodingName{\oldstylenums{4}}
345 \DeclareTextCommand{\textfiveoldstyle} \UnicodeEncodingName{\oldstylenums{5}}
346 \DeclareTextCommand{\textsixoldstyle} \UnicodeEncodingName{\oldstylenums{6}}
347 \DeclareTextCommand{\textsevenoldstyle} \UnicodeEncodingName{\oldstylenums{7}}
348 \DeclareTextCommand{\texteightoldstyle} \UnicodeEncodingName{\oldstylenums{8}}
349 \DeclareTextCommand{\textnineoldstyle} \UnicodeEncodingName{\oldstylenums{9}}
```

These have Unicode slots so this should be integrated into TU explicitly

```
350 \DeclareTextSymbol{\textpilcrow} \UnicodeEncodingName{"00B6}
351 \DeclareTextSymbol{\textborn} \UnicodeEncodingName{"002A}
352 \DeclareTextSymbol{\textdied} \UnicodeEncodingName{"2020}
353 \DeclareTextSymbol{\textlbrackdbl} \UnicodeEncodingName{"27E6}
354 \DeclareTextSymbol{\textrbrackdbl} \UnicodeEncodingName{"27E7}
355 \DeclareTextSymbol{\textguarani} \UnicodeEncodingName{"20B2}
```

We could make `\textcentoldstyle` and `\textdollaroldstyle` point to dollar and cent in the Unicode encoding

```
356 %\DeclareTextSymbol{\textcentoldstyle} \UnicodeEncodingName{"00A2}
357 %\DeclareTextSymbol{\textdollaroldstyle}\UnicodeEncodingName{"0024}
```

but I think it is better to pick them up from TS1 even if that usually means LMR fonts

```
358 \DeclareTextSymbol{\textdollaroldstyle}{TS1}{138}
359 \DeclareTextSymbol{\textcentoldstyle} {TS1}{139}

360 \fi % --- END of Unicode engines specials
```

### 3 Font family sub-encodings setup

We declare the subsets for a good number of fonts in the kernel ...

But first the default for anything that is not declared. We use 9 which is most likely much too conservative, but with the advantage that we aren't getting missing glyphs (or at least that this is very unlikely). For nearly all font in the T<sub>E</sub>X Live distribution of 2019 “correct” classifications are given below, so that this default is only used for new font families, and over time the right classifications can be added here too.

```
361 \DeclareEncodingSubset{TS1}{?}{9}
```

This first block contains the fonts that have been already supported by the `textcomp` package way back, i.e., the font families that have T<sub>E</sub>X support since the mid-nineties.

```
362 \DeclareEncodingSubset{TS1}{ccr} {0}
363 \DeclareEncodingSubset{TS1}{cmbr} {0}
```

The following 4 declarations are now part of the corresponding `.fd` file, hopefully other will follow so that this list of declarations can eventually be removed from the kernel (where it doesn't belong).

```
364 %\DeclareEncodingSubset{TS1}{cmr} {0}
365 %\DeclareEncodingSubset{TS1}{cmss} {0}
366 %\DeclareEncodingSubset{TS1}{cmtt} {0}
367 %\DeclareEncodingSubset{TS1}{cmvtt} {0}

368 \DeclareEncodingSubset{TS1}{cmtl} {0}
369 \DeclareEncodingSubset{TS1}{pxr} {0}
370 \DeclareEncodingSubset{TS1}{pxss} {0}
371 \DeclareEncodingSubset{TS1}{pxtt} {0}
372 \DeclareEncodingSubset{TS1}{qag} {0}
373 \DeclareEncodingSubset{TS1}{qbk} {0}
374 \DeclareEncodingSubset{TS1}{qcr} {0}
375 \DeclareEncodingSubset{TS1}{qcs} {0}
376 \DeclareEncodingSubset{TS1}{qhvc} {0}
377 \DeclareEncodingSubset{TS1}{qhv} {0}
378 \DeclareEncodingSubset{TS1}{qpl} {0}
379 \DeclareEncodingSubset{TS1}{qtm} {0}
380 \DeclareEncodingSubset{TS1}{qzc} {0}
381 \DeclareEncodingSubset{TS1}{txr} {0}
382 \DeclareEncodingSubset{TS1}{txss} {0}
383 \DeclareEncodingSubset{TS1}{txtt} {0}

384 \DeclareEncodingSubset{TS1}{lmr} {1}
385 \DeclareEncodingSubset{TS1}{lmdh} {1}
386 \DeclareEncodingSubset{TS1}{lmss} {1}
387 \DeclareEncodingSubset{TS1}{lmssq} {1}
```

```
388 \DeclareEncodingSubset{TS1}{lmvtt} {1}
```

The lmtt family is missing TM, SM, and perthousand for some reason, so the first safe sub-encoding would be 2, but that is then missing out a huge number of glyphs that are available, so we claim it is sub-encoding 1 even if this can lead to missing glyphs.

```
389 \DeclareEncodingSubset{TS1}{lmtt} {1} % missing TM, SM and pertentousand
```

The next three families have been removed from TeX Live, but we keep the definitions

```
390 \DeclareEncodingSubset{TS1}{ptmx} {2}
```

```
391 \DeclareEncodingSubset{TS1}{ptmj} {2}
```

```
392 \DeclareEncodingSubset{TS1}{ul8} {2}
```

The next set are the early PostScript font implementations, these days there are better alternatives, but .... Note that, their virtual fonts contain a lot of “tofu” in form of black squares, thus they don’t even give a missing character warning if you select such a glyph. This is why they are set as sub-encoding 5.

```
393 \DeclareEncodingSubset{TS1}{bch} {5} % tofu for blank, ohm
```

```
394 \DeclareEncodingSubset{TS1}{futj} {5} % tofu for blank, interrobang/down, ohm
```

```
395 \DeclareEncodingSubset{TS1}{futs} {5} % tofu for blank, ohm
```

```
396 \DeclareEncodingSubset{TS1}{futex} {5} % probably (currently broken distrib)
```

```
397 \DeclareEncodingSubset{TS1}{pag} {5} % tofu for blank, interrobang/down, ohm
```

```
398 \DeclareEncodingSubset{TS1}{pbk} {5} % tofu for blank, interrobang/down, ohm
```

```
399 \DeclareEncodingSubset{TS1}{pcr} {5} % tofu for blank, interrobang/down, ohm
```

```
400 \DeclareEncodingSubset{TS1}{phv} {5} % tofu for blank, interrobang/down, ohm
```

```
401 \DeclareEncodingSubset{TS1}{pnc} {5} % tofu for blank, interrobang/down, ohm
```

```
402 \DeclareEncodingSubset{TS1}{pplj} {5} % tofu for blank
```

```
403 \DeclareEncodingSubset{TS1}{pplx} {5} % tofu for blank
```

```
404 \DeclareEncodingSubset{TS1}{ppl} {5} % tofu for blank interrobang/down
```

```
405 \DeclareEncodingSubset{TS1}{ptm} {5} % tofu for blank, interrobang/down, ohm
```

```
406 \DeclareEncodingSubset{TS1}{pzc} {5} % tofu for blank, interrobang/down, ohm
```

```
407 \DeclareEncodingSubset{TS1}{ul9} {5} % tofu for blank, interrobang/down, ohm
```

The next set suffers from the same problem and they contain even fewer real glyphs.

```
408 \DeclareEncodingSubset{TS1}{dayroms} {6} % tofu for blank, interrobang/down, ohm
```

```
409 \DeclareEncodingSubset{TS1}{dayrom} {6} % tofu for blank, interrobang/down, ohm
```

```
410 \DeclareEncodingSubset{TS1}{augie} {8} % really only missing euro
```

```
411 \DeclareEncodingSubset{TS1}{put} {8}
```

```
412 \DeclareEncodingSubset{TS1}{uag} {8} % probably (currently broken distrib)
```

```
413 \DeclareEncodingSubset{TS1}{ugq} {8}
```

```
414 \DeclareEncodingSubset{TS1}{zi4} {9}
```

LucidaBright (sold through TUG) probably not quite correct, I guess as I have the older fonts ...

```
415 \DeclareEncodingSubset{TS1}{hls} {5}
```

```
416 \DeclareEncodingSubset{TS1}{hlst} {5}
```

```
417 \DeclareEncodingSubset{TS1}{hlct} {5}
```

```
418 \DeclareEncodingSubset{TS1}{hlh} {5}
```

```
419 \DeclareEncodingSubset{TS1}{hlx} {8}
```

```
420 \DeclareEncodingSubset{TS1}{hlce} {8}
```

```
421 \DeclareEncodingSubset{TS1}{hlcn} {8}
```

```
422 \DeclareEncodingSubset{TS1}{hlcw} {8}
```

```
423 \DeclareEncodingSubset{TS1}{hlcf} {8}
```

Below are the newer fonts that have support files for L<sup>A</sup>T<sub>E</sub>X. With very few exceptions the classifications are done so that all characters are correctly produced (either being available in the font or substituted).

There are a few fonts that contain “tofu” squares in places (instead of a real glyph) and in a few cases some really seldom needed chars are unavailable, i.e., produce missing glyphs (to avoid that a large number of available chars are unnecessarily substituted).

Encoding declarations for these font families shouldn’t really be in the kernel, but part of the .fd files for the family. When we introduced the concept in 2021 we had some hope that this would happen over time and that we could take the declarations out—after all it is nearly impossible to maintain it correctly in the kernel, given that fonts may get new glyphs added (happened for several of them in the recent year) which is something we wouldn’t notice. However, so far this hasn’t happened, so in 2024, I went through the current set and adjusted the declarations in several places.

Next four are wrong and still need adjustment:

```

424 \DeclareEncodingSubset{TS1}{lato-*}      {0} % with a bunch of tofu inside
425 \DeclareEncodingSubset{TS1}{opensans-*}  {0} % with a bunch of tofu inside
426 \DeclareEncodingSubset{TS1}{cantarell-*} {0} % with a bunch of tofu inside
427 \DeclareEncodingSubset{TS1}{tli}         {1} % with lots of tofu inside
428 \DeclareEncodingSubset{TS1}{fbb-*}       {2} % missing centoldstyle

429 \DeclareEncodingSubset{TS1}{Alegreya-*}      {2}
430 \DeclareEncodingSubset{TS1}{AlegreyaSans-*}  {2}
431 \DeclareEncodingSubset{TS1}{BaskervilleF-*}  {2}
432 \DeclareEncodingSubset{TS1}{DejaVuSans-TLF}  {2}
433 \DeclareEncodingSubset{TS1}{DejaVuSansCondensed-TLF} {2}

```

Next one is missing \textfractionsolidus but is otherwise completely sub-encoding 2 so we use that sub-encoding.

```

434 \DeclareEncodingSubset{TS1}{DejaVuSansMono-TLF}      {2}

435 \DeclareEncodingSubset{TS1}{EBGaramond-*}             {2}
436 \DeclareEncodingSubset{TS1}{Merriwthr-OsF}            {2}
437 \DeclareEncodingSubset{TS1}{MerriwthrSans-OsF}        {2}
438 \DeclareEncodingSubset{TS1}{Montserrat-*}             {2}

538 \DeclareEncodingSubset{TS1}{LibertinusMono-TLF} {8}
539 \DeclareEncodingSubset{TS1}{AlgolRevived-TLF} {9}

```

## 4 Legacy symbol support for lists and footnote symbols

`\UseLegacyTextSymbols`

```

540 \def\UseLegacyTextSymbols{%
541   \DeclareTextSymbolDefault{\textasteriskcentered}{OMS}%
542   \DeclareTextSymbolDefault{\textbardbl}{OMS}%
543   \DeclareTextSymbolDefault{\textbullet}{OMS}%
544   \DeclareTextSymbolDefault{\textdaggerdbl}{OMS}%
545   \DeclareTextSymbolDefault{\textdagger}{OMS}%
546   \DeclareTextSymbolDefault{\textparagraph}{OMS}%
547   \DeclareTextSymbolDefault{\textperiodcentered}{OMS}%
548   \DeclareTextSymbolDefault{\textsection}{OMS}%
549   \UndeclareTextCommand{\textsection}{T1}%
550   \expandafter\let\csname oldstylenums \expandafter\endcsname
551     \csname legacyoldstylenums \endcsname
552 }

```

(End of definition for \UseLegacyTextSymbols.)

\textlegacyasteriskcentered Here are new names for the legacy symbols that L<sup>A</sup>T<sub>E</sub>X used to pick up from the OMS encoded fonts (and used for itemize lists or footnote symbols).

\textlegacybardbl We go the roundabout way via separate OMS declarations so that

\textlegacybullet \renewcommand\textbullet{\textlegacybullet}

\textlegacydaggerdbl doesn't produce an endless loop.

\textlegacydagger \DeclareTextSymbol{\textlegacyasteriskcentered}{OMS}{3} % "03  
\textlegacyparagraph \DeclareTextSymbol{\textlegacybardbl}{OMS}{107} % "6B  
\textlegacyperiodcentered \DeclareTextSymbol{\textlegacybullet}{OMS}{15} % "0F  
\textlegacysection \DeclareTextSymbol{\textlegacydaggerdbl}{OMS}{122} % "7A  
\DeclareTextSymbol{\textlegacydagger}{OMS}{121} % "79  
\DeclareTextSymbol{\textlegacyparagraph}{OMS}{123} % "7B  
\DeclareTextSymbol{\textlegacyperiodcentered}{OMS}{1} % "01  
\DeclareTextSymbol{\textlegacysection}{OMS}{120} % "78  
\DeclareTextSymbolDefault{\textlegacyasteriskcentered}{OMS}  
\DeclareTextSymbolDefault{\textlegacybardbl}{OMS}  
\DeclareTextSymbolDefault{\textlegacybullet}{OMS}  
\DeclareTextSymbolDefault{\textlegacydaggerdbl}{OMS}  
\DeclareTextSymbolDefault{\textlegacydagger}{OMS}  
\DeclareTextSymbolDefault{\textlegacyparagraph}{OMS}  
\DeclareTextSymbolDefault{\textlegacyperiodcentered}{OMS}  
\DeclareTextSymbolDefault{\textlegacysection}{OMS}

(End of definition for \textlegacyasteriskcentered and others.)

## 5 The textcomp package

For any rollback request before 2018-08-11 we make an attempt by loading the 2018 version.

```

774 \*TS1sty
775 \DeclareRelease{}{1997-12-01}{textcomp-2018-08-11.sty}
776 \DeclareRelease{}{2018-08-11}{textcomp-2018-08-11.sty}
777 \DeclareCurrentRelease{}{2020-02-02}
778
779 \ProvidesPackage{textcomp}
780 [2024/04/24 v2.1b Standard LaTeX package]

```

A precaution in case this is used without rebuilding the format.

```

781 \NeedsTeXFormat{LaTeX2e}[2020/02/02]

```

This is implemented by defining the default subset:

```

782 \DeclareOption{full}{\DeclareEncodingSubset{TS1}{?}{0}}
783 \DeclareOption{almostfull}{\DeclareEncodingSubset{TS1}{?}{1}}
784 \DeclareOption{euro}{\DeclareEncodingSubset{TS1}{?}{8}}
785 \DeclareOption{safe}{\DeclareEncodingSubset{TS1}{?}{9}}

```

The default is set up in the kernel is “safe” these days for unknown fonts but LaTeX has definitions for most families so it seldom applies.

If a different default is used then one needs to check the results to ensure that there aren’t “missing glyphs”.

The next set of options define the warning level (default in the kernel is info only). Using the package options you can change this behavior.

```

786 \DeclareOption{error}
787 {\gdef\tc@errorwarn{\PackageError{textcomp}}}
788 \DeclareOption{warn}
789 {\gdef\tc@errorwarn#1#2{\PackageWarning{textcomp}{#1}}}
790 \DeclareOption{info}
791 {\gdef\tc@errorwarn#1#2{\PackageInfo{textcomp}{#1}}}
792 \DeclareOption{quiet}{\gdef\tc@errorwarn#1#2{}}

```

The “force” option basically changes the sub-encoding to that of the default (which, unless changes, is 9 these days), i.e., it no longer depends on the font in use. This is mainly there because it might have been used in older documents, but not something that is recommended.

```

793 \DeclareOption{force}{%
794   \def\CheckEncodingSubset#1#2#3#4#5{%
795     \ifnum #4>%
796       0\csname #2:\endcsname
797       \relax
798     \expandafter\@firstoftwo
799   \else
800     \expandafter\@secondoftwo
801   \fi
802   {#1{#2}}{#3}%
803   #5}%
804 }

805 \ProcessOptions\relax

```

There is not much else to do nowadays, because everything is already set up in the L<sup>A</sup>T<sub>E</sub>X kernel.

```

806 \InputIfFileExists{textcomp.cfg}
807 {\PackageInfo{textcomp}{Local configuration file used}}{}
808 </TS1sty>

```

## 5.1 The old textcomp package code

This section contains the old code for the textcomp package and its documentation. It is only used if we roll back prior to 2020. Thus all the rest is mainly for historians. Note that the old code categorized in the sub-encodings only into 6 classes not 10.

```

809 <*TS1oldsty>
810 \ProvidesPackage{textcomp}
811 [2018/08/11 v2.0j Standard LaTeX package]

```

This one is for the TS1 encoding which contains text symbols for use with the T1-encoded text fonts. It therefore first inputs the file `TS1enc.def` and then sets (or resets) the defaults for the symbols it contains. The result of this is that when one of these symbols is accessed and the current encoding does not provide it, the symbol will be supplied by a silent, local change to this encoding.

Since many PostScript fonts only implement a subset of TS1 many commands only produce black blobs of ink. To resolve the resulting problems a number of options have been introduced and some code has been developed to distinguish sub-encodings.

The sub-encodings have a numerical id and are defined as follows for TS1:

**#5** those TS1 symbols that are also in the ISO-Adobe character set; without `textcurrency`, which is often misused for the Euro. Older Type1 fonts from the non-T<sub>E</sub>X world provide only this subset.

**#4** = #5 + `\texteuro`. Most newer fonts provide this.

**#3** = #4 + `\textomega`. Can also be described as  $TS1 \cap (ISO-Adobe \cup MacRoman)$ . (Except for the missing “currency”.)

**#2** = **#3** + `\textestimated` + `\textcurrency`. Can also be described as `TS1`  $\cap$  Adobe-Western-2. This may be relevant for OpenType fonts, which usually show the Adobe-Western-2 character set.

**#1** = `TS1` without `\textcircled` and `\t`. These two glyphs are often not implemented and if their kernel defaults are changed commands like `\copyright` unnecessarily fail.

**#0** = full `TS1`

And here a summary to go in the transcript file:

```

812 \PackageInfo{textcomp}{Sub-encoding information:\MessageBreak
813   \space\space 5 = only ISO-Adobe without
814                     \string\textcurrency\MessageBreak
815   \space\space 4 = 5 + \string\texteuro\MessageBreak
816   \space\space 3 = 4 + \string\textohm\MessageBreak
817   \space\space 2 = 3 + \noexpand\textestimated+
818                     \string\textcurrency\MessageBreak
819   \space\space 1 = TS1 - \noexpand\textcircled-
820                     \string\t\MessageBreak
821   \space\space 0 = TS1 (full)\MessageBreak
822   Font families with sub-encoding setting implement\MessageBreak
823   only a restricted character set as indicated.\MessageBreak
824   Family '?' is the default used for unknown fonts.\MessageBreak
825   See the documentation for details\@gobble}

```

`\DeclareEncodingSubset` An encoding subset to which a font family belongs is declared by the command `\DeclareEncodingSubset` that takes the major encoding as the first argument (e.g., `TS1`), the family name as the second argument (e.g., `cmr`), and the subset encoding id as a third, (e.g., 0 for `cmr`).

The default encoding subset to use when nothing is known about the current font family is named `?`.

```

826 \def\DeclareEncodingSubset#1#2#3{%
827   \@ifundefined{#1:#2}%
828     {\PackageInfo{textcomp}{Setting #2 sub-encoding to #1/#3}}%
829     {\PackageInfo{textcomp}{Changing #2 sub-encoding to #1/#3}}%
830   \@namedef{#1:#2}{#3}}

```

In the original code this was only allowed in the preamble but now `.fds` might contain it so that even in a rollback situation it is necessary to allow it everywhere in the document.

```

831 %\@onlypreamble\DeclareEncodingSubset

```

(End of definition for `\DeclareEncodingSubset`.)

The options for the package are the following:

**safe** for unknown font families enables only symbols that are also in the ISO-Adobe character set; without "currency", which is often misused for the Euro. Older Type1 fonts from the non-TeX world provide only this subset.

**euro** enables the “safe” symbols plus the `\texteuro` command. Most newer fonts provide this.

**full** enables all `TS1` commands; useful only with fonts like EC or CM bright.

**almostfull** same as “full”, except that `\textcircled` and `\t` are *not* redefined from their defaults to avoid that commands like `\copyright` suddenly no longer work.

**force** ignore all subset encoding definitions stored in the package itself or in the configuration file and always use the default subset as specified by one of the other options (seldom useful, only dangerous).

`\iftc@forced` Switch used to implement the **force** option

```
832 \newif\iftc@forced \tc@forcedfalse
```

(End of definition for `\iftc@forced`.)

This is implemented by defining the default subset:

```
833 \DeclareOption{full}{\DeclareEncodingSubset{TS1}{?}{0}}
```

```
834 \DeclareOption{almostfull}{\DeclareEncodingSubset{TS1}{?}{1}}
```

```
835 \DeclareOption{euro}{\DeclareEncodingSubset{TS1}{?}{4}}
```

```
836 \DeclareOption{safe}{\DeclareEncodingSubset{TS1}{?}{5}}
```

The default is “almostfull” which means that old documents will work except that `\textcircled` and `\t` will use the kernel defaults (with the advantage that this also works if the current font, as often the case, doesn’t implement these glyphs).

The “force” option simply sets the switch to true.

```
837 \DeclareOption{force}{\tc@forcedtrue}
```

The suggestions to user is to use the “safe” option always unless that balks in which case they could switch to “almostfull” but then better check their output manually.

```
838 \def\tc@errorwarn{\PackageError}
```

```
839 \DeclareOption{warn}{\gdef\tc@errorwarn#1#2#3{\PackageWarning{#1}{#2}}}
```

```
840 \DeclareOption{quiet}{\gdef\tc@errorwarn#1#2#3{}}
```

```
841 \ExecuteOptions{almostfull}
```

```
842 \ProcessOptions\relax
```

`\CheckEncodingSubset` The command `\CheckEncodingSubset` will check if the current font family has the right encoding subset to typeset a certain command. It takes five arguments as follows: first argument is either `\UseTextSymbol`, `\UseTextAccent` depending on whether or not the symbol is a text symbol or a text accent.

The second argument is the encoding from which this symbol should be fetched.

The third argument is either a fake accessor command or an error message. the code in that argument (if ever executed) receives two arguments: **#2** and **#5** of `\CheckEncodingSubset`.

Argument four is the subset encoding id to test against: if this value is higher than the subset id of the current font family then we typeset the symbol, i.e., execute **#1{#2}#5** otherwise it runs **#3#5**, e.g., to produce an error message or fake the glyph somehow.

Argument five is the symbol or accent command that is being checked.

For usage examples see definitions below.

```
843 \iftc@forced
```

If the “force” option was given we always use the default for testing against.

```
844 \def\CheckEncodingSubset#1#2#3#4#5{%
```

```
845   \ifnum #4>%
```

```
846     0\csname #2:\endcsname
```

```
847     \relax
```

```
848   \expandafter\@firstoftwo
```

```
849   \else
```

```

850 \expandafter\@secondoftwo
851 \fi
852 {#1{#2}}{#3}%
853 #5%
854 }

```

In normal circumstances the test is a bit more complicated: first check if there exists a macro `\(arg2):⟨current-family⟩` and if so use that value to test against, otherwise use the default to test against.

```

855 \else
856 \def\CheckEncodingSubset#1#2#3#4#5{%
857   \ifnum #4>%
858     \expandafter\ifx\csname #2:\f@family\endcsname\relax
859       0\csname #2:?\endcsname
860     \else
861       \csname #2:\f@family\endcsname
862     \fi
863   \relax
864   \expandafter\@firstoftwo
865 \else
866   \expandafter\@secondoftwo
867 \fi
868 {#1{#2}}{#3}%
869 #5%
870 }
871 \fi

```

*(End of definition for \CheckEncodingSubset.)*

`\tc@subst`

```

872 \def\tc@subst#1{%
873   \tc@errorwarn{textcomp}%
874   {Symbol \string#1 not provided by\MessageBreak
875     font family \f@family\space
876     in TS1 encoding.\MessageBreak Default family used instead}\@eha
877   \bgroup\fontfamily\textcompsubstdefault\selectfont#1\egroup
878 }

```

*(End of definition for \tc@subst.)*

`\tc@error` `\tc@error` is going to be used in arg #3 of `\CheckEncodingSubset` when a symbol is not available in a certain font family. It gets pass the encoding it normally lives in (arg one) and the name of the symbol or accent that has a problem.

```

879 % error commands take argument:
880 % #1 symbol to be used
881 \def\tc@error#1{%
882   \PackageError{textcomp}% % should be latex error if general
883   {Accent \string#1 not provided by\MessageBreak
884     font family \f@family\space
885     in TS1 encoding}\@eha
886 }

```

*(End of definition for \tc@error.)*

`\tc@fake@euro` `\tc@fake@euro` is an example of a “fake” definition to use in arg #3 of `\CheckEncodingSubset` when a symbol is not available in a certain font family. Here we produce an Euro symbol by combining a “C” with a “=”.

```

887 \def\tc@fake@euro#1{%
888   \leavevmode
889   \PackageInfo{textcomp}{Faking \noexpand#1for font family
890                                     \f@family\MessageBreak in TS1 encoding}%
891   \valign{##\cr
892         \vfil\hbox to 0.07em{\dimen@\f@size\p@
893                                     \math@fontsfalse
894                                     \fontsize{.7\dimen@}\z@\selectfont=\hss}%
895         \vfil\cr%
896         \hbox{C}\crrcr
897   }%
898 }
```

*(End of definition for \tc@fake@euro.)*

`\tc@check@symbol` These are two abbreviations that we use below to check symbols and accents in TS1.  
`\tc@check@accent` Only there to save some space, e.g., we can then write

```
DeclareTextCommandDefault{\textcurrency}{\tc@check@symbol3\textcurrency}
```

to ensure that `\textcurrency` is only typeset if the current font has a TS1 subset id of less than 3. Otherwise `\tc@error` is called telling the user that for this font family `\textcurrency` is not available.

```

899 \def\tc@check@symbol{\CheckEncodingSubset\UseTextSymbol{TS1}\tc@subst}
900 \def\tc@check@accent{\CheckEncodingSubset\UseTextAccent{TS1}\tc@error}
```

*(End of definition for \tc@check@symbol and \tc@check@accent.)*

We start with the commands that are “safe” and which can be unconditionally set up, first the accents...

```

901 \DeclareTextAccentDefault{\capitalcedilla}{TS1}
902 \DeclareTextAccentDefault{\capitalogonek}{TS1}
903 \DeclareTextAccentDefault{\capitalgrave}{TS1}

1083 {\tc@check@symbol2\textsurd}

```

The `\textcircled` and `\t` are handled specially, unless the current font has a subset id of 0 (i.e. full TS1) we pick the symbols up from the math font encodings, i.e., the third argument to `\CheckEncodingSubset` uses `\UseTextAccent` to get them from there.

```

1084 \DeclareTextCommandDefault{\textcircled}
1085 {\CheckEncodingSubset\UseTextAccent{TS1}%
1086 {\UseTextAccent{OMS}}1\textcircled}
1087 \DeclareTextCommandDefault{\t}
1088 {\CheckEncodingSubset\UseTextAccent{TS1}%
1089 {\UseTextAccent{OML}}1\t}

```

Finally input the encoding-specific definitions for TS1 thus making the top-level definitions optimized for this encoding (and not for the default encoding).

```

1090 \input{ts1enc.def}

```

Now having the new glyphs available we also want to make sure that they are used. For most cases this will automatically happen but for some glyphs there are inferior definitions already known to L<sup>A</sup>T<sub>E</sub>X which will prevent the usage of the TS1 versions. So we better get rid of them:

```

1091 \UndeclareTextCommand{\textsterling}{OT1}
1092 \UndeclareTextCommand{\textdollar} {OT1}

```

Similar declarations should probably be made for other encodings like OT4 if they are in use.

```

1093 %\UndeclareTextCommand{\textsterling}{OT4}
1094 %\UndeclareTextCommand{\textdollar} {OT4}

```

From the T1 encoding there are two candidates for removal: `%0` and `%00` since these are both constructed from `%` followed by a tiny ‘`o`’ rather than being a single glyph. The problem with this approach is that in PostScript fonts this small zero is usually not available resulting in `%■` rather than `%0` while the real glyph (at least for `\textperthousand`) is available in the PostScript version of TS1. So for the moment we compromise by removing the T1 declaration for `\textperthousand` but keeping the one for `\textpertenthousand`. This will have the effect that with Computer Modern fonts everything will come out (although `%0` and `%00` are not taken from the same physical font) and with PostScript fonts `%00` will come out correctly while `%000` will most likely look like `%■` — which is probably an improvement over just getting a single ‘`■`’ to indicate a completely missing glyph, which would happen if we also ‘undeclared’ `\textpertenthousand`.

```

1095 \UndeclareTextCommand{\textperthousand}{T1}
1096 %\UndeclareTextCommand{\textpertenthousand}{T1}

```

### 5.1.1 Supporting oldstyle digits

```

1097 \DeclareRobustCommand\oldstylenums[1]{%
1098   \begingroup
1099   \ifmmode
1100     \mathgroup\symletters #1%
1101   \else
1102     \CheckEncodingSubset\@use@text@encoding{TS1}%
1103     {\PackageWarning{textcomp}%
1104      {Oldstyle digits unavailable for
1105       family \f@family.\MessageBreak
1106       Lining digits used instead}}%
1107     \tw@{#1}%
1108   \fi
1109   \endgroup
1110 }

```

### 5.1.2 Subset encoding defaults

For many font families commonly used in the T<sub>E</sub>X world we provide the subset encoding data here. Users can add additional font families in the file `textcomp.cfg` if they own other fonts.

However, if the option “forced” was given then all subset encoding specifications are ignored, so there is no point in setting any of them up:

```

1111 \iftc@forced \else
      Computer modern based fonts (e.g., CM, CM-Bright, Concrete):
1112 \DeclareEncodingSubset{TS1}{cmr}      {0}
1113 \DeclareEncodingSubset{TS1}{cmss}     {0}
1114 \DeclareEncodingSubset{TS1}{cmtt}     {0}
1115 \DeclareEncodingSubset{TS1}{cmvtt}    {0}
1116 \DeclareEncodingSubset{TS1}{cmbr}     {0}
1117 \DeclareEncodingSubset{TS1}{cmtl}     {0}
1118 \DeclareEncodingSubset{TS1}{ccr}      {0}
      PSNFSS fonts:
1119 \DeclareEncodingSubset{TS1}{ptm}      {4}
1120 \DeclareEncodingSubset{TS1}{pcr}      {4}
1121 \DeclareEncodingSubset{TS1}{phv}      {4}
1122 \DeclareEncodingSubset{TS1}{ppl}      {3}
1123 \DeclareEncodingSubset{TS1}{pag}      {4}
1124 \DeclareEncodingSubset{TS1}{pbk}      {4}
1125 \DeclareEncodingSubset{TS1}{pnc}      {4}
1126 \DeclareEncodingSubset{TS1}{pzc}      {4}
1127 \DeclareEncodingSubset{TS1}{bch}      {4}
1128 \DeclareEncodingSubset{TS1}{put}      {5}
      Other CTAN fonts (probably not complete):
1129 \DeclareEncodingSubset{TS1}{uag}      {5}
1130 \DeclareEncodingSubset{TS1}{ugq}      {5}
1131 \DeclareEncodingSubset{TS1}{ul8}      {4}
1132 \DeclareEncodingSubset{TS1}{ul9}      {4} % (LuxiSans, one day)
1133 \DeclareEncodingSubset{TS1}{augie}    {5}
1134 \DeclareEncodingSubset{TS1}{dayrom}    {3}
1135 \DeclareEncodingSubset{TS1}{dayroms}  {3}
1136 \DeclareEncodingSubset{TS1}{pxr}      {0}

```

```

1137 \DeclareEncodingSubset{TS1}{pxss}    {0}
1138 \DeclareEncodingSubset{TS1}{pxtt}    {0}
1139 \DeclareEncodingSubset{TS1}{txr}      {0}
1140 \DeclareEncodingSubset{TS1}{txss}     {0}
1141 \DeclareEncodingSubset{TS1}{txtt}     {0}

```

Latin Modern and TeX Gyre:

```

1142 \DeclareEncodingSubset{TS1}{lmr}      {0}
1143 \DeclareEncodingSubset{TS1}{lmdh}     {0}
1144 \DeclareEncodingSubset{TS1}{lmss}     {0}
1145 \DeclareEncodingSubset{TS1}{lmssq}    {0}
1146 \DeclareEncodingSubset{TS1}{lmvtt}    {0}
1147 \DeclareEncodingSubset{TS1}{lmtt}     {0}

1148 \DeclareEncodingSubset{TS1}{qhv}      {0}
1149 \DeclareEncodingSubset{TS1}{qag}      {0}
1150 \DeclareEncodingSubset{TS1}{qbk}      {0}
1151 \DeclareEncodingSubset{TS1}{qcr}      {0}
1152 \DeclareEncodingSubset{TS1}{qcs}      {0}
1153 \DeclareEncodingSubset{TS1}{qpl}      {0}
1154 \DeclareEncodingSubset{TS1}{qtm}      {0}
1155 \DeclareEncodingSubset{TS1}{qzc}      {0}
1156 \DeclareEncodingSubset{TS1}{qhvc}     {0}

```

Fourier-GUTenberg:

```

1157 \DeclareEncodingSubset{TS1}{futs}     {4}
1158 \DeclareEncodingSubset{TS1}{futex}    {4}
1159 \DeclareEncodingSubset{TS1}{futj}     {4}

```

Y&Y's Lucida Bright

```

1160 \DeclareEncodingSubset{TS1}{hlh}      {3}
1161 \DeclareEncodingSubset{TS1}{hls}      {3}
1162 \DeclareEncodingSubset{TS1}{hlst}     {3}

```

The remaining settings for Lucida are conservative: the following fonts contain the `\textohm` character but not the `\texteuro`, i.e., belong to neither subset 4 nor subset 3. If you want to use the `\textohm` with these fonts copy these definition to `textcomp.cfg` and change the subset to 3. However in that case make sure that you do not use the `\texteuro`.

```

1163 \DeclareEncodingSubset{TS1}{hlct}     {5}
1164 \DeclareEncodingSubset{TS1}{hlx}      {5}
1165 \DeclareEncodingSubset{TS1}{hlce}     {5}
1166 \DeclareEncodingSubset{TS1}{hlcn}     {5}
1167 \DeclareEncodingSubset{TS1}{hlcw}     {5}
1168 \DeclareEncodingSubset{TS1}{hlcf}     {5}

```

Other commercial families...

```

1169 \DeclareEncodingSubset{TS1}{pplx}     {3}
1170 \DeclareEncodingSubset{TS1}{pplj}     {3}
1171 \DeclareEncodingSubset{TS1}{ptmx}     {4}
1172 \DeclareEncodingSubset{TS1}{ptmj}     {4}

```

If the file `textcomp.cfg` exists it will be loaded at this point. This allows to define further subset encodings for font families not covered by default.

```

1173 \InputIfFileExists{textcomp.cfg}
1174 {\PackageInfo{textcomp}{Local configuration file used}}{}

```

```

1175 \fi
1176 \end{TS1oldsty}

```

## 6 The checkencodingsubset.tex file

This is a simple file that asks for a name of a font family and then displays information about the TS1 encoding for this family and recommends the right encoding subset (to be used with `\DeclareEncodingsubset`) for this family.

```

1177 (*TS1check)
1178 \ProvidesFile{checkencodingsubset.tex}
1179 [2024/10/18 v0.5b Figure out safe TS1 encoding subsets]

1180 \let\typeoutdetails\typeout
1181 %\def\typeoutdetails#1{} % alternative definition used below

```

For the purpose of this check a glyph exists if the font slot is occupied—too bad if that contains the wrong glyph or some tofu. If it “exists” we return 0 otherwise 1. This way we can call this macro several times in a row and obtain a number that is 0 if all glyphs are existing or greater than 0 if any of them is missing.

The second argument (holding the command name for a symbol) is not used during these tests.

```

1182 \def\doesglyphexist#1#2{\iffontchar\testFont #1 0\else 1\relax \fi}

```

This macro also tests and outputs some information about the symbol if it is missing. This time we make use of the second argument.

```

1183 \def\glyphmissingdetails#1#2{\iffontchar\testFont #1 \else
1184   \typeoutdetails{\space\space\space ==> \string#2 (#1) is missing}\fi}

1185 \newif\ifsafesubencodingfound
1186 \newif\ifcoremisses

```

Testing a group of symbols that belong to one sub-encoding. More precisely, the symbols that become unavailable if you change from sub-encoding  $x$  (#2) to  $x + 1$  (#3). As far as the code is concerned, the symbols that are supposed to be always available (the core) become available if we test the group -1 and 0.

The first argument contains the testing code and is supposed to return a single number greater or equal to zero.

```

1187 \def\testgroup#1#2#3{%
1188   \ifnum 0 = #1%
1189     \ifnum #2<0
1190       \typeoutdetails{All glyphs in core exist}%
1191     \else
1192       \typeoutdetails{All glyphs between sub-encoding #2 and #3 exist}%
1193     \fi
1194   \else
1195     \ifnum #2<0
1196       \typeoutdetails{*****}%
1197       \typeoutdetails{Some glyphs are missing from core:}%
1198       \coremisstrue
1199       \ifsafesubencodingfound \else
1200         \def\subencodingresult{#2}%
1201       \fi
1202     \else

```

```

1203     \typeoutdetails{Some glyphs are missing from sub-encoding #2:}%
1204     \ifsafesubencodingfound \else
1205         \def\subencodingresult{#3}%
1206     \fi
1207 \fi

```

If some glyphs are missing, we rerun the test code but this time using `\glyphmissingdetails`.

```

1208     {\let\doesglyphexist \glyphmissingdetails #1}%

```

And because we had misses we have definitely found the subset.

```

1209     \safesubencodingfoundtrue
1210 \fi
1211 }

```

The currently defined subset for the family is either stored in `\TS1:<family>` if it was declared, or it is the default subset which is stored in `\TS1:?`.

```

1212 \def\currsubencoding#1{\csname TS1:\ifcsname TS1:#1\endcsname #1\else ?\fi\endcsname}

```

If a font family is not found when declaring it with `\DeclareFixedFont` we end up with the following font. This can then be used as a simple test if we failed loading the TS1 font.

```

1213 \DeclareFixedFont\cmrFont{TS1}{cmr}{m}{n}{10pt}
    Check for all glyphs in all encoding subsets ...
1214 \def\testallgroups#1{%
1215     \DeclareFixedFont\testFont{TS1}{#1}{m}{n}{10pt}%
1216     \ifx\testFont\cmrFont
1217         \typeout{***** Font family #1 not found ****}%
1218     \else

```

We haven't checked anything yet.

```

1219     \safesubencodingfoundfalse
1220     \coremissesfalse
1221     \typeoutdetails{^^J-----}%
1222     \typeoutdetails{Testing font family #1^^J(currently TS1-sub-encoding
1223         \currsubencoding{#1})}%
1224     \typeout{-----}%

```

Then we start testing the groups beginning with the glyphs between sub-encoding 8 and 9. If any of them is missing (checked with `\doesglyphexist`) then we already know that 9 is the correct answer.

```

1225     \testgroup{%
1226         \doesglyphexist{21}{\texttwelveudash}%
1227         \doesglyphexist{22}{\textthreequartersemdash}%
1228         \doesglyphexist{134}{\textbardbl}%
1229         \doesglyphexist{137}{\textcelsius}%
1230         \doesglyphexist{178}{\texttwosuperior}%
1231         \doesglyphexist{179}{\textthreesuperior}%
1232         \doesglyphexist{185}{\textonesuperior}%
1233     }{8}{9}%

```

Nevertheless we go on with further groups so that the output lists all missing glyphs.

```

1234     \testgroup{%
1235         \doesglyphexist{32}{\textblank}%
1236         \doesglyphexist{148}{\textinterrobang}%

```

All fonts (up to now) that belong to sub-encoding 1 do have the `\textcircled` glyph, but it is too small to be usable. So this test for this group currently doesn't do much good—but who knows maybe one day a font shows up in which this glyph is actually missing.

## 1 Page Numbering

Page numbers are produced by a page counter, used just like any other counter. The only difference is that `\c@page` contains the number of the next page to be output (the one currently being produced), rather than one minus it. Thus, it is normally initialized to 1 rather than 0. `\c@page` is defined to be `\count0`, rather than a count assigned by `\newcount`.

`\pagenumbering` The user sets the page number style with the `\pagenumbering{<foo>}` command, which sets the page counter to 1 and defines `\thepage` to be `\foo`. For example, `\pagenumbering{roman}` causes pages to be numbered i, ii, etc.

```
1 <*2ekernel>
2 \message{page nos.,}

3 \countdef\c@page=0 \c@page=1
4 \def\c1@page{}
5 \def\pagenumbering#1{%
6   \global\c@page \c@one \gdef\thepage{\csname @#1\endcsname
7     \c@page}}
8 </2ekernel>
```

## File 35

# ltxref.dtx

## 1 Cross Referencing

The user writes `\label{foo}` to define the following cross-references:

`\ref*{foo}`: value of most recently incremented referenceable counter. in the current environment. (Chapter, section, theorem, footnote and enumeration counters and other counters stepped with `\refstepcounter` are referenceable.)

`\pageref*{foo}`: page number at which `\label{foo}` command appeared. where `foo` can be any string of characters not containing `\`, `{` or `}`.

Note: The scope of the `\label` command is delimited by environments, so `\begin{theorem} \label{foo} ... \end{theorem} \label{bar}` defines `\ref{foo}` to be the theorem number and `\ref{bar}` to be the current section number.

Note: `\label` does the right thing in terms of spacing – i.e., leaving a space on both sides of it is equivalent to leaving a space on either side.

Note: the starred versions `\ref*` and `\pageref*` are provided to align with the use of `hyperref`. Without `hyperref` (or some other package using the starred form) the star is simply ignored.

Note: starting with 2023-06-01 `\label` stores also the current value of `\@currentlabelname` which should typically contain a (sanitized) title. (A reference command `\nameref` is provided by the `nameref` package.) `\label` also stores `\@currentHref` which if set should refer to a target name for links. This value is set and used by `hyperref`. Unlike the other values `\@currentHref` should be set globally. A fifth value `\@kernel@reserved@label@data` is reserved for the kernel to allow future extensions of the cross-reference system.

### 1.1 Cross Referencing

*Historical L<sup>A</sup>T<sub>E</sub>X 2.09 comments (not necessarily accurate any more):*

```
1 <*2ekernel>
2 \message{x-ref,}
```

This is implemented as follows. A referenceable counter `CNT` is incremented by the command `\refstepcounter{CNT}`, which sets `\@currentlabel == {CNT}{eval(\p@cnt\theCNT)}`. The command `\label{FOO}` then writes the following on file `\@auxout`:

```
\newlabel{FOO}{eval(\@currentlabel)}{eval(\thepage)}%
```

```
{eval(\@currentlabelname)}{eval(\@currentHref)}{eval(\@kernel@reserved@label@data)}
```

```
\ref{FOO} ==
BEGIN
  if \r@foo undefined
  then @refundefined := G T
  ??
  Warning: 'reference foo on page ... undefined'
```

```

        else \@car \eval(\r@F00)\@nil
      fi
    END

\pageref{foo} =
  BEGIN
    if \r@foo undefined
    then @refundundefined := G T
      ??
      Warning: 'reference foo on page ... undefined'
    else \@cdr \eval(\r@F00)\@nil
    fi
  END

```

*End of historical L<sup>A</sup>T<sub>E</sub>X 2.09 comments.*

**\labelformat** A reference via **\ref** produces by default the data associated with the corresponding **\label** command (typically a number); any additional formatting has to be provided by the user. If, for example, references to equations are always to be typeset as “equation (*number*)”, one has to code “**equation** (**\ref{key}**)”.

With **\labelformat** there is a possibility to generate such frills automatically without resorting to low-level coding. The command takes two arguments: the first is the name of a counter and the second is its representation when referenced. This means that for a successful usage, one has to know the counter name being used for generating the label, though in practice this should not pose a problem. The current counter number is picked up as an argument. Here are two examples:

```

\labelformat{section}{section~#1}
\labelformat{equation}{equation~( #1 )}

```

**\Ref** A side effect of using **\labelformat** is that, depending on the defined formatting, it becomes impossible to use **\ref** at the beginning of a sentence (if its replacement text starts with a lowercase letter). To overcome this problem we introduce the command **\Ref** that behave like **\ref** except that it uppercases the first token of the generated string.

To make **\Ref** work properly the very first token in the second argument of **\labelformat** has to be a simple ASCII or UTF-8 letter, otherwise the capitalization will fail or worse, you will end up with some error messages. If you actually need something more complicated in this place (e.g., an accented letter not written as a UTF-8 character) you have to explicitly surround it with braces, to identify the part that needs to be capitalized. For example, for figure references in the Hungarian language you might want to write **\labelformat{figure}{\’a}bra~\thefigure** or use **\labelformat{figure}{ábra~\thefigure}** which avoids the brace problem.

**\G@refundundefinedtrue** This does not save on name-space (since **\G@refundundefinedfalse** was never needed) but it does make the implementation of such one-way switches more consistent. The extra macro to make the change is used since this change appears several times.

**Note** despite its name, **\G@refundundefinedtrue** does *not* correspond to an **\if** command, and there is no matching **...false**. It would be more natural to call the command **\G@refundundefined** (as inspection of the change log will reveal) but unfortunately such a change would break any package that had defined a **\ref**-like command that mimicked the definition of **\ref**, calling **\G@refundundefinedtrue**. Inspection of the T<sub>E</sub>X archives

revealed several such packages, and so this command has been named ...`true` so that the definition of `\ref` need not be changed, and the packages will work without change.

```

3 % \newif\ifG@refundefined
4 % \def\G@refundefinedtrue{\global\let\ifG@refundefined\iftrue}
5 % \def\G@refundefinedfalse{\global\let\ifG@refundefined\iffalse}
6 \def\G@refundefinedtrue{%
7   \gdef\@refundefined{%
8     \@latex@warning@no@line{There were undefined references}}
9 \let\@refundefined\relax

```

(End of definition for `\G@refundefinedtrue` and `\@refundefined`.)

`\ref` Referencing a `\label`. RmS 91/10/25: added a few extra `\reset@font`, as suggested by  
`\pageref` Bernd Raichle  
`\setref` RmS 92/08/14: made `\ref` and `\pageref` robust  
RmS 93/09/08: Added setting of `refundefined` switch.

81 <latexrelease>
82 <latexrelease>\EndIncludeInRelease
83 <*2ekernel>

```

*(End of definition for \ref, \pageref, and \@setref.)*

`\newlabel` This command will be written to the `.aux` file to pass label information from one run to another.

`\@newl@bel` The internal form of `\newlabel` and `\bibcite`. Note that this macro does its work inside a group. That way the local assignments it needs to do don't clutter the save stack. This prevents large documents with many labels to run out of save stack.

```

84 \def\@newl@bel#1#2#3{%
85   \ifundefined{#1#2}%
86     \relax
87     {\gdef \@multiplelabels {%
88       \@latex@warning@no@line{There were multiply-defined labels}}}%

```

```

89 \latex@warning@no@line{Label ‘#2’ multiply defined}}%
90 \global\@namedef{#1@#2}{#3}}
91 \def\newlabel{\@newl@bel r}
92 \onlypreamble{\@newl@bel

```

*(End of definition for \newlabel and \@newl@bel.)*

`\if@multiplelabels` This is redefined to produce a warning if at least one label is defined more than once. It is executed by the `\enddocument` command.

```

93 \let \@multiplelabels \relax

```

*(End of definition for \if@multiplelabels and \@multiplelabels.)*

`\label` The commands `\label` and `\refstepcounter` have been changed to allow `\protect`’ed commands to work properly. For example,

```

\def\thechapter{\protect\foo{\arabic{chapter}.\roman{section}}}

```

will cause a `\label{bar}` command to define `\ref{bar}` to expand to something like `\foo{4.d}`. Change made 20 Jul 88.

```

117 \<latexrelease> {\@currentHref}{set theHcounter representation}%

```

`refstepcounter` (*socket*) This socket takes the whole code as argument. The default kernel plug is identity. By changing the plug `hyperref` can add a conditional and e.g. suppress the processing in a PDF context.

```
118 \NewSocket{refstepcounter}{1}
```

`refstepcounter/target` (*socket*) This socket takes an argument, the counter name, and should at least set from it the target name `\@currentHref`. With `hyperref` it sets also the actual target. This is done with a socket so that the target name is not set more than once to (possibly) different names. The socket is not used in `\@kernel@refstepcounter`. The tagging code needs the target name so it is added after this socket.

```
119 \NewSocket{refstepcounter/target}{1}
```

`(refstepcounter/target)` (*plug*)

```
120 \NewSocketPlug{refstepcounter/target}{kernel}
121 {\xdef\@currentHref {#1.\csname theH#1\endcsname}}%
122 \AssignSocketPlug{refstepcounter/target}{kernel}

123 \def\refstepcounter#1{%
124   \UseSocket{refstepcounter}{%
125     \stepcounter{#1}%
126     \edef\reserved@a{#1}%
127     \ifx\reserved@a\ltx@star@counter\else
128       \let\@currentcounter\reserved@a
129     \fi
130     \protected@edef\@currentlabel
```

By generating the second `csname` first the `\p@...` command can grab it as an argument which can be helpful for more complicated typesetting arrangements.

The trick is to ensure that `\csname the#1\endcsname` is turned into a single token before `\p@...` is expanded further. This way, if the `\p@...` command is a macro with one argument it will receive `\the...`. With the original kernel code (i.e., without the `\expandafter`) it will instead pick up `\csname` which would be disastrous.

Using `\expandafter` instead of braces delimiting the argument is better because, assuming that the `\p@...` command is not defined as a macro with one argument, the braces will stay and prohibit kerning that might otherwise happen between the glyphs generated by `\the...` and surrounding glyphs.

```
131     {\csname p@#1\expandafter\endcsname\csname the#1\endcsname}%
132     \UseSocket{refstepcounter/target}{#1}%
133     \UseTaggingSocket{recordtarget}%
134   }%
135 }
```

This is a version of `\refstepcounter` which does not set and use targets.

```
\@kernel@refstepcounter 136 \def\@kernel@refstepcounter#1{%
137   \UseSocket{refstepcounter}{%
138     \stepcounter{#1}%
139     \edef\reserved@a{#1}%
140     \ifx\reserved@a\ltx@star@counter\else
141       \let\@currentcounter\reserved@a
142     \fi
143     \protected@edef\@currentlabel

## File 36

# ltproperties.dtx

### Abstract

This code implements command to record and (expandably) reference document properties. It extends the standard `\label/\ref/\pageref` commands.

## 1 Introduction

The module allows to record the “current state” of various document properties (typically the content of macros and values of counters) and to access them in other places through a label. The list of properties that can be recorded and retrieved are not fix and can be extended by the user. The values of the properties are recorded in the `.aux` file and can be retrieved at the second compilation.

The module uses the ideas of properties and labels. A label is a document reference point: a name for the user. An property is something that  $\text{\LaTeX}$  can track, such as a page number, section number or name. The names of labels and properties may be arbitrary. Note that there is a single namespace for each.

## 2 Design discussion

The design here largely follows ideas from `zref`. In particular, there are two independent concepts: properties that can be recorded between runs, and labels which consist of lists of these properties. The reason for the split is that individual labels will want to record some but not all properties. For examples, a label concerned with position would track the  $x$  and  $y$  coordinates of the current point, but not for example the page number.

In the current implementation, properties share a single namespace. This allows multiple lists to re-use the same properties, for example page number, absolute page number, etc. This does mean that *changing* a standard property is an issue. However, some properties have complex definitions (again, see `zref` at present): having them in a single shared space avoids the need to copy code.

Labels could be implemented as `prop` data. That is not done at present as there is no obvious need to map to or copy the data. As such, faster performance is available using a hash table approach as in a “classical” set up. Data written to the `.aux` file uses simple paired *balanced text* not keyvals: this avoids any restrictions on names and again offers increased performance.

The `expl3` versions of the label command do not use `\@bsphack/\@esphack` to avoid double spaces, but the  $\text{\LaTeX} 2_{\epsilon}$  command does as it lives at the document command level.

The reference commands are expandable.

Currently the code has nearly no impact on the main `\label` and `\ref` commands as too many external packages rely on the concrete implementation. There is one exception: the label names share the same namespace. That means that if both `\label{ABC}` and `\RecordProperties{ABC}{page}` are used there is a warning Label ‘ABC’ multiply defined.

### 3 Handling unknown labels and properties

With the standard `\label/\ref` commands the requested label is either in the `.aux`-file (and so known) or not. In the first case the stored value can be used, in the second case the reference commands print two question marks.

With flexible property lists a reference commands asks for the value of a specific property stored under a label name and we have to consider more variants:

- If the requested property is unknown (not declared) the system is not correctly set up and an error is issued.
- If the label is unknown, the default of the property is used.
- If the label is known, but doesn't provide a value for the property then again the default of the property is used.
- The command `\property_ref:nnn` allows to give a local default which is used instead of the property default in the two cases before.

### 4 Rerun messages

As the reference commands are expandable they can neither issue a message that the label or the label-property combination is unknown, nor can they trigger the rerun message at the end of the  $\text{\LaTeX}$  run.

Where needed such messages must therefore be triggered manually. For this two commands are provided: `\property_ref_undefined_warn:` and `\property_ref_undefined_warn:nn`. See below for a description.

### 5 Open points

- The `xpos` and `ypos` properties require that the position is stored first but there is no (public) engine independent interface yet. Code must use `\tex_savepos:D`.

### 6 Code interfaces

---

<code>\property_new:nnnn</code>	<code>\property_new:nnnn {&lt;property&gt;} {&lt;setpoint&gt;} {&lt;default&gt;} {&lt;code&gt;}</code>
<code>\property_gset:nnnn</code>	<code>\property_gset:nnnn {&lt;property&gt;} {&lt;setpoint&gt;} {&lt;default&gt;} {&lt;code&gt;}</code>

---

$\text{\LaTeX} 2_{\epsilon}$ -interface: see `\NewProperty`, `\SetProperty`.

Sets the `<property>` to have the `<default>` specified, and at the `<setpoint>` (either `now` or `shipout`) to write the result of the `<code>` as part of a label. The `<code>` should be expandable. The expansion of `<code>` (the value of the property) is written to the `.aux` file and read back from there at the next compilation. Values should assume that the standard  $\text{\LaTeX}$  catcode régime with `@` a letter is active then.

If the property is declared within a package it is suggested that its name is build from letters, hyphens and slashes, and is always structured as follows:  
`<package-name>/<property-name>`.

---

<code>\property_record:nN</code>	<code>\property_record:nN {&lt;label&gt;} &lt;clist var&gt;</code>
<code>\property_record:nn</code>	<code>\property_record:nn {&lt;label&gt;} {&lt;clist&gt;}</code>
<code>\property_record:(nV ee)</code>	<p>LaTeX 2<sub>ε</sub>-interface: see <code>\RecordProperties</code>.</p> <p>Writes the list of properties given by the <code>&lt;clist&gt;</code> to the <code>.aux</code> file with the <code>&lt;label&gt;</code> specified.</p>

---

<code>\property_ref:nn *</code>	<code>\property_ref:nn {&lt;label&gt;} {&lt;property&gt;}</code>
<code>\property_ref:ee *</code>	<p>LaTeX 2<sub>ε</sub>-interface: see <code>\RefProperty</code>.</p> <p>Expands to the value of the <code>&lt;property&gt;</code> for the <code>&lt;label&gt;</code>, if available, and the default value of the property otherwise. If <code>&lt;property&gt;</code> has not been declared with <code>\property_new:nnnn</code> an error is issued. The command raises an internal, expandable, local flag if the reference can not be resolved.</p>

---

<code>\property_ref:nnn *</code>	<code>\property_ref:nnn {&lt;label&gt;} {&lt;property&gt;} {&lt;local default&gt;}</code>
<code>\property_ref:een *</code>	<p>LaTeX 2<sub>ε</sub>-interface: see <code>\RefProperty</code>.</p> <p>Expands to the value of the <code>&lt;property&gt;</code> for the <code>&lt;label&gt;</code>, if available, and to <code>&lt;local default&gt;</code> otherwise. If <code>&lt;property&gt;</code> has not been declared with <code>\property_new:nnnn</code> an error is issued. The command raises an internal, expandable local flag if the reference can not be resolved.</p>

---

<code>\property_ref_undefined_warn:</code>	<code>\property_ref_undefined_warn:</code>
--	--

LaTeX 2<sub>ε</sub>-interface: not provided.

Triggers the standard warning

LaTeX Warning: There were undefined references.

at the end of the document if there was a recent `\property_ref:nn` or `\property_ref:nnn` which couldn't be resolved and so raised the flag. "Recent" means in the same group or in some outer group!

---

<code>\property_ref_undefined_warn:n</code>	<code>\property_ref_undefined_warn:n {&lt;label&gt;}</code>
<code>\property_ref_undefined_warn:e</code>	

LaTeX 2<sub>ε</sub>-interface: not provided.

Triggers the standard warning

LaTeX Warning: There were undefined references.

at the end of the document if `<label>` is not known. At the point where it is called it also issues the warning

Reference '`<label>`' on page `<page>` undefined.

---

<code>\property_ref_undefined_warn:nn</code>	<code>\property_ref_undefined_warn:nn {&lt;label&gt;} {&lt;property&gt;}</code>
<code>\property_ref_undefined_warn:ee</code>	

LaTeX 2<sub>ε</sub>-interface: see `\RefUndefinedWarn`.

Triggers the standard warning

LaTeX Warning: There were undefined references.

at the end of the document if the reference can not be resolved. At the point where it is called it also issues the warning

Reference '`<label>`' on page `<page>` undefined

if the label is unknown, or the more specific

Property '`<property>`' undefined for reference '`<label>`' on page `<page>`

if the label is known but doesn't provide a value for the requested property.

---

<code>\property_if_exist_p:n</code>	<code>* \property_if_exist_p:n {&lt;property&gt;}</code>
<code>\property_if_exist_p:e</code>	<code>* \property_if_exist:nTF {&lt;property&gt;} {&lt;true code&gt;} {&lt;false code&gt;}</code>
<code>\property_if_exist:nTF</code>	<code>* L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub>-interface: \IfPropertyExistsTF.</code>
<code>\property_if_exist:eTF</code>	<code>* Tests if the &lt;property&gt; has been declared.</code>
<hr/>	
<code>\property_if_recorded_p:n</code>	<code>* \property_if_recorded_p:n {&lt;label&gt;}</code>
<code>\property_if_recorded_p:e</code>	<code>* \property_if_recorded:nTF {&lt;label&gt;} {&lt;true code&gt;} {&lt;false code&gt;}</code>
<code>\property_if_recorded:nTF</code>	<code>* </code>
<code>\property_if_recorded:eTF</code>	<code>* </code>
<hr/>	
	L <sup>A</sup> T <sub>E</sub> X 2 <sub>ε</sub> -interface: \IfLabelExistsTF
	Tests if the <label> is known. This is also true if the label has been set with the standard \label command.
<hr/>	
<code>\property_if_recorded_p:nn</code>	<code>* \property_if_recorded_p:nn {&lt;label&gt;} {&lt;property&gt;}</code>
<code>\property_if_recorded_p:ee</code>	<code>* \property_if_recorded:nnTF {&lt;label&gt;} {&lt;property&gt;} {&lt;true code&gt;} {&lt;false code&gt;}</code>
<code>\property_if_recorded:nnTF</code>	<code>* </code>
<code>\property_if_recorded:eeTF</code>	<code>* </code>
<hr/>	
	L <sup>A</sup> T <sub>E</sub> X 2 <sub>ε</sub> -interface: \IfPropertyRecordedTF.
	Tests if the label <label> is known and if it provides a value of the <property>.

## 7 Auxiliary file interfaces

<hr/>	
<code>\new@label@record</code>	<code>\new@label@record {&lt;label&gt;} {&lt;data&gt;}</code>
<hr/>	
	This is a command only for use in the .aux file. It loads the key–value list of <data> to be available for the <label>.

## 8 L<sup>A</sup>T<sub>E</sub>X 2<sub>ε</sub> interface

The L<sup>A</sup>TeXe interfaces always expand label and property arguments. This means that one must be careful when using active chars or commands in the names. UTF8-chars are protected and should be safe, similar most babel shorthands.

<hr/>	
<code>\NewProperty</code>	<code>\NewProperty {&lt;property&gt;} {&lt;setpoint&gt;} {&lt;default&gt;} {&lt;code&gt;}</code>
<code>\SetProperty</code>	<code>\SetProperty {&lt;property&gt;} {&lt;setpoint&gt;} {&lt;default&gt;} {&lt;code&gt;}</code>
<hr/>	
	Sets the <property> to have the <default> specified, and at the <setpoint> (either now or shipout) to write the result of the <code> as part of a label. The <code> should be expandable. The expansion of <code> (the value of the property) is written to the .aux file and read back from there at the next compilation (at which point normally the standard L <sup>A</sup> T <sub>E</sub> X catcode régime with @ a letter is active).
<hr/>	
<code>\RecordProperties</code>	<code>\RecordProperties {&lt;label&gt;} {&lt;clist&gt;}</code>
<hr/>	
	Writes the list of properties given by the <clist> to the .aux file with the <label> specified. Similar to the standard \label command the arguments are expanded. So <clist> can be a macro containing a list of properties. Also similar to the standard \label command, the command is surrounded by an \@bsphack/\@esphack pair to preserve spacing.

<hr/> <b>\RefProperty</b> *	<b>\RefProperty</b> [ <i>\local default</i> ] { <i>\label</i> } { <i>\property</i> }
	Expands to the value of the <i>\property</i> for the <i>\label</i> , if available, and the default value of the property or – if given – to <i>\local default</i> otherwise. If { <i>\property</i> } has not been declared an error is issued.
<hr/> <b>\IfPropertyExistsTF</b> <b>\IfPropertyExistsT</b> <b>\IfPropertyExistsF</b>	<b>\IfPropertyExistsTF</b> { <i>\property</i> } { <i>true code</i> } { <i>false code</i> }
	Tests if the <i>\property</i> has been declared.
<hr/> <b>\IfLabelExistsTF</b> <b>\IfLabelExistsT</b> <b>\IfLabelExistsF</b>	<b>\IfLabelExistsTF</b> { <i>\label</i> } { <i>true code</i> } { <i>false code</i> }
	Tests if the <i>\label</i> has been recorded. This is also true if a label has been set with the standard <code>\label</code> command.
<hr/> <b>\IfPropertyRecordedTF</b> <b>\IfPropertyRecordedT</b> <b>\IfPropertyRecordedF</b>	<b>\IfPropertyRecordedTF</b> { <i>\label</i> } { <i>\property</i> } { <i>true code</i> } { <i>false code</i> }
	Tests if the label and a value of the <i>\property</i> for the <i>\label</i> are both known.
<hr/> <b>\RefUndefinedWarn</b>	<b>\RefUndefinedWarn</b> { <i>\label</i> } { <i>\property</i> }
	Triggers the standard warning <p>LaTeX Warning: There were undefined references.</p> at the end of the document if the reference for <i>\label</i> and <i>\property</i> can not be resolved. At the point where it is called it also issues the warning <p>Reference ‘<i>\label</i>’ on page <i>\page</i> undefined</p> if the label is unknown, or the more specific <p>Property ‘<i>\property</i>’ undefined for reference ‘<i>\label</i>’ on page <i>\page</i></p> if the label is known but doesn’t provide a value for the requested property.

## 9 Pre-declared properties

<hr/> <b>abspage</b>	(shipout) The absolute value of the current page: starts at 1 and increases monotonically at each shipout.
<hr/> <b>page</b>	(shipout) The current page as given by <code>\thepage</code> : this may or may not be a numerical value, depending on the current style. Contrast with <code>\abspage</code> . You get this value also with the standard <code>\label/\pageref</code> .
<hr/> <b>pagenum</b>	(shipout) The current page as arabic number. This is suitable for integer operations and comparisons.
<hr/> <b>label</b>	(now) The content of <code>\@currentlabel</code> . This is the value that you get also with the standard <code>\label/\ref</code> .

<u>title</u>	(now) The content of <code>\@currentlabelname</code> . This command is filled beside others by the <code>nameref</code> package and some classes (e.g. <code>memoir</code> ).
<u>target</u>	(now) The content of <code>\@currentHref</code> . This command is normally filled by for example <code>hyperref</code> and gives the name of the last destination it created.
<u>pagetarget</u>	(shipout) The content of <code>\@currentHpage</code> . This command is filled for example by a recent version of <code>hyperref</code> and then gives the name of the last page destination it created.
<u>counter</u>	(now) The content of <code>\@currentcounter</code> . This command contains after a <code>\refstepcounter</code> the name of the counter.
<u>xpos</u> <u>ypos</u>	(shipout) This stores the $x$ and $y$ coordinates of a point previously stored with <code>\pdfsavepos</code> / <code>\savepos</code> . E.g. (if <code>bidi</code> is used it can be necessary to save the position before and after the label):

```

\text_savepos:D
\property_record:nn{myposition}{xpos,ypos}
\text_savepos:D

```

## 10 The Implementation

```

1 <*2ekernel | latexrelease>
2 \ExplSyntaxOn
3 <@@=property>
4 <latexrelease>\NewModuleRelease{2023/11/01}{ltproperties}
5 <latexrelease>                                {Cross-referencing~properties}

```

The approach here is based closely on that from `zref`; separate out lists of properties and the properties themselves, so the latter can be used multiple times and in varying combinations. However, not everything is a straight copy. Firstly, we treat lists of properties as simple comma lists: that allows us to have either saved or dynamic lists and to avoid another data structure. The cost is that errors are detected at point-of-use, but in any real case that should be true anyway (and is true for `\zref@labelbyprop` already). Secondly, we allow properties to have arbitrary names, as the code does not require them to tokenize as control sequences.

`\property_new:nnnn` As properties can be reset, they are not constants. But they also have various pieces  
`\property_gset:nnnn` of required data. So we use the same approach as `color` and make them declarations.  
`\__property_gset:nnnn` Data-wise, we need the detail of the implementation, the default and a flag to show if  
the code works now or at shipout. This last entry is done using `text` so needs a check.  
We could use a set of `prop` here, but as we never need to map or copy the lists, we can  
gain performance using the hash table approach.

```

6 \cs_new_protected:Npn \property_new:nnnn #1#2#3#4

```

```

7   {
8     \cs_if_free:cTF { __property_code_ #1 : }
9     {
10      \exp_args:Nx \__property_gset:nnnn { \tl_to_str:n {#1} }
11      {#2} {#3} {#4}
12    }
13    {
14      \msg_error:nn { property }{ exists }{#1}
15    }
16  }
17  \cs_new_protected:Npn \property_gset:nnnn #1#2#3#4
18  {
19    \__property_gset:ennn { \tl_to_str:n {#1} }
20    {#2} {#3} {#4}
21  }
22  \cs_new_protected:Npn \__property_gset:nnnn #1#2#3#4
23  {
24    \cs_gset:cpn { __property_code_ #1 : } {#4}
25    \tl_gclear_new:c { g__property_default_ #1 _tl }
26    \tl_gset:cn { g__property_default_ #1 _tl } {#3}
27    \bool_if_exist:cF { g__property_shipout_ #1 _bool }
28    { \bool_new:c { g__property_shipout_ #1 _bool } }
29    \str_case:nnF {#2}
30    {
31      { now } { { \bool_gset_false:c { g__property_shipout_ #1 _bool } } }
32      { shipout }
33      { \bool_gset_true:c { g__property_shipout_ #1 _bool } }
34    }
35    { \msg_error:nnnn { property } { unknown-setpoint } {#1} {#2} }
36  }
37  \cs_generate_variant:Nn \__property_gset:nnnn {ennn}

```

(End of definition for \property\_new:nnnn, \property\_gset:nnnn, and \\_\_property\_gset:nnnn.  
These functions are documented on page 815.)

**\NewProperty** For consistency we expand the property name, but this doesn't warrant a variant of the  
**\SetProperty** L3-commands.

```

38  \cs_new_protected:Npn \NewProperty #1#2#3#4
39  {
40    \protected@edef\reserved@a{#1}
41    \exp_args:No \property_new:nnnn {\reserved@a} {#2}{#3}{#4}
42  }
43  \cs_new_protected:Npn \SetProperty #1#2#3#4
44  {
45    \protected@edef\reserved@a{#1}
46    \exp_args:No \property_gset:nnnn {\reserved@a} {#2}{#3}{#4}
47  }

```

(End of definition for \NewProperty and \SetProperty. These functions are documented on page 817.)

**\property\_record:nN** Writing data when it is labelled means expanding at this stage and possibly later too.  
**\property\_record:nn** That is all pretty easy using expl3: we accept a stray comma at the end of the list as  
**\property\_record:nV** that is easier to deal with than trying to tidy up, and there is no real downside.

```

48  \cs_new_protected:Npn \property_record:nN #1#2

```

```

\property_record:oo
\__property_record:nn
\__property_record:en
\__property_record_value:n
  \_property_record_value_aux:n
  \_property_record_value_aux:e

```

```

49 { \property_record:nV {#1} #2 }
50 \cs_new_protected:Npn \property_record:nn #1#2
51 { \__property_record:en { \tl_to_str:n {#1} } {#2} }
52 \cs_generate_variant:Nn \property_record:nn { nV , ee, oo }
53 \cs_new_protected:Npn \__property_record:nn #1#2
54 {
55   \protected@write \@auxout {}
56   {
57     \token_to_str:N \new@label@record
58     {#1}
59     { \clist_map_function:nN {#2} \__property_record_value:n }
60   }
61 }
62 \cs_generate_variant:Nn \__property_record:nn { e }
63 \cs_new:Npn \__property_record_value:n #1
64 { \__property_record_value_aux:e { \tl_to_str:n {#1} } }
65 \cs_new:Npn \__property_record_value_aux:n #1
66 {
67   \cs_if_exist:cTF { __property_code_ #1 : }
68   {
69     {#1}
70     {
71       \bool_if:cTF { g__property_shipout_ #1 _bool }
72       { \exp_not:c }
73       { \use:c }
74       { __property_code_ #1 : }
75     }
76   }
77   { \msg_expandable_error:nnn { property } { not-declared } {#1} }
78 }
79 \cs_generate_variant:Nn \__property_record_value_aux:n { e }

```

(End of definition for `\property_record:nN` and others. These functions are documented on page 816.)

## **\RecordProperties**

```

80 \NewDocumentCommand\RecordProperties { m m }
81 {
82   \@bsphack
83   \protected@edef\reserved@a{#1}
84   \protected@edef\reserved@b{#2}
85   \property_record:oo {\reserved@a}{\reserved@b}
86   \@esphack
87 }

```

(End of definition for `\RecordProperties`. This function is documented on page 817.)

## **10.1 Reference commands**

`l__property_ref_flag` A flag that is set if a reference couldn't be resolved.

```

88 \flag_new:n { l__property_ref_flag }

```

(End of definition for `l__property_ref_flag`.)

**\property\_ref:nn** Search for the label/property combination, and if not found fall back to the default of the property.

```

89 \cs_new:Npn \property_ref:nn #1#2
90 {
91   \__property_ref:een
92   { \tl_to_str:n {#1} }
93   { \tl_to_str:n {#2} }
94   { \tl_use:c { g__property_default_ #2 _tl } }
95 }
96 \cs_generate_variant:Nn \property_ref:nn {ee}

```

(End of definition for \property\_ref:nn. This function is documented on page 816.)

**\property\_ref:nnn** This allows to set a local default value which overrides the default value of the property.

**\property\_ref:een**

**\\_\_property\_ref:nnn**

**\\_\_property\_ref:een**

```

97 \cs_new:Npn \property_ref:nnn #1#2#3
98 {
99   \__property_ref:een
100   { \tl_to_str:n {#1} }
101   { \tl_to_str:n {#2} }
102   {#3}
103 }
104 \cs_new:Npn \__property_ref:nnn #1#2#3
105 {
106   \tl_if_exist:cTF { g__property_label_ #1 _ #2 _tl }
107   { \tl_use:c { g__property_label_ #1 _ #2 _tl } }
108   {
109     \flag_if_raised:nF
110     { l__property_ref_flag } { \flag_raise:n { l__property_ref_flag } }

```

We test for the default of the property only to check if the property has been declared.

```

111   \tl_if_exist:cTF { g__property_default_ #2 _tl }
112   { #3 }
113   { \msg_expandable_error:nnn { property } { not-declared } {#2} }
114 }
115 }
116 \cs_generate_variant:Nn \__property_ref:nnn { ee }
117 \cs_generate_variant:Nn \property_ref:nnn { een}

```

(End of definition for \property\_ref:nnn and \\_\_property\_ref:nnn. This function is documented on page 816.)

**\RefProperty** Search for the label/property combination, and if not found fall back to the default of the property or the given default.

```

118 \NewExpandableDocumentCommand \RefProperty { o m m }
119 {
120   \IfNoValueTF {#1}
121   {
122     \property_ref:ee {#2}{#3}
123   }
124   {
125     \property_ref:een {#2}{#3}{#1}
126   }
127 }

```

(End of definition for \RefProperty. This function is documented on page 818.)

```

\new@label@record A standard recursion loop.
\__property_data:nnn
128 \cs_new_protected:Npn \new@label@record #1#2
129 {
130   \tl_if_exist:cTF { r@#1 }
131   {
132     \gdef \@multiplelabels
133     { \@latex@warning@no@line { There-were-multiply-defined-labels } }
134     \@latex@warning@no@line { Label-‘#1’~multiply-defined }
135   }
136   {
137     \tl_new:c { r@#1 }
138     \tl_gset:cn { r@#1 }{#2}
139   }
140   \__property_data:nnn {#1} #2 { \q_recursion_tail } { ? } \q_recursion_stop
141 }
142 \cs_new_protected:Npn \__property_data:nnn #1#2#3
143 {
144   \quark_if_recursion_tail_stop:n {#2}
145   \tl_gclear_new:c { g__property_label_ \tl_to_str:n {#1} _ \tl_to_str:n {#2} _tl }
146   \tl_gset:cn { g__property_label_ \tl_to_str:n {#1} _ \tl_to_str:n {#2} _tl } {#3}
147   \__property_data:nnn {#1}
148 }

This command is used in \enddocument to test if some label values have changed.
149 \cs_new_protected:Npn \@kernel@new@label@record@testdef #1 #2
150 {
151   \tl_if_eq:cnF { r@#1 } {#2}
152   { \@tempwattrue }
153 }

```

(End of definition for \new@label@record and \\_\_property\_data:nnn. This function is documented on page 817.)

## 10.2 Tests and warnings

```

\property_if_exist_p:n Tests if property has been declared.
\property_if_exist:nTF
154 \prg_new_conditional:Npnn \property_if_exist:n #1 { p , T , F , TF }
155 % #1 property
156 {
157   \cs_if_exist:cTF { __property_code_ #1 : }
158   {
159     \prg_return_true:
160   }
161   {
162     \prg_return_false:
163   }
164 }
165 \prg_generate_conditional_variant:Nnn \property_if_exist:n {e} { p , T , F , TF }

(End of definition for \property_if_exist:nTF. This function is documented on page 817.)

```

```

\IfPropertyExistsTF
\IfPropertyExistsT
\IfPropertyExistsF
166 \cs_new_eq:NN \IfPropertyExistsTF \property_if_exist:eTF
167 \cs_new:Npn \IfPropertyExistsT #1#2 {\property_if_exist:eTF {#1}{#2}{}}
168 \cs_new:Npn \IfPropertyExistsF #1 {\property_if_exist:eTF {#1}{}}

```

(End of definition for `\IfPropertyExistsTF`, `\IfPropertyExistsT`, and `\IfPropertyExistsF`. These functions are documented on page 818.)

`\property_if_recorded_p:n` Tests if the label has been set. This can then be used to setup e.g. rerun messages.

```

\property_if_recorded:nTF
169 \prg_new_conditional:Npnn \property_if_recorded:n #1 { p , T , F , TF }
170   % #1 label
171   {
172     \tl_if_exist:cTF { r@#1 }
173     {
174       \prg_return_true:
175     }
176     {
177       \prg_return_false:
178     }
179   }
180 \prg_generate_conditional_variant:Nnn \property_if_recorded:n {e} { p , T , F , TF }

```

(End of definition for `\property_if_recorded:nTF`. This function is documented on page 817.)

`\IfLabelExistsTF`  
`\IfLabelExistsT`  
`\IfLabelExistsF`

```

181 \cs_new_eq:NN \IfLabelExistsTF \property_if_recorded:eTF
182 \cs_new:Npn \IfLabelExistsT #1#2 { \property_if_recorded:eTF {#1}{#2}{ } }
183 \cs_new:Npn \IfLabelExistsF #1 { \property_if_recorded:eTF {#1}{ } }

```

(End of definition for `\IfLabelExistsTF`, `\IfLabelExistsT`, and `\IfLabelExistsF`. These functions are documented on page 818.)

`\property_if_recorded_p:nn` tests if the label/property combination has been set This can then be used to setup  
`\property_if_recorded:nnTF` e.g. rerun messages.

```

184 \prg_new_conditional:Npnn \property_if_recorded:nn #1#2 { p , T , F , TF }
185   % #1 label #2 property
186   {
187     \tl_if_exist:cTF { g__property_label_ \tl_to_str:n {#1} _ \tl_to_str:n {#2} _tl }
188     {
189       \prg_return_true:
190     }
191     {
192       \prg_return_false:
193     }
194   }
195 \prg_generate_conditional_variant:Nnn \property_if_recorded:nn {ee} { p , T , F , TF }

```

(End of definition for `\property_if_recorded:nnTF`. This function is documented on page 817.)

`\IfPropertyRecordedTF`  
`\IfPropertyRecordedT`  
`\IfPropertyRecordedF`

```

196 \cs_new_eq:NN \IfPropertyRecordedTF \property_if_recorded:eeTF
197 \cs_new:Npn \IfPropertyRecordedT #1#2#3 { \property_if_recorded:eeTF {#1}{#2}{#3}{ } }
198 \cs_new:Npn \IfPropertyRecordedF #1#2#3 { \property_if_recorded:eeTF {#1}{#2}{ }{#3} }

```

(End of definition for `\IfPropertyRecordedTF`, `\IfPropertyRecordedT`, and `\IfPropertyRecordedF`. These functions are documented on page 818.)

`\property_ref_undefined_warn:` `\G@refundefinedtrue` is defined in `ltxref` and redefines a warning message.

```
199 \cs_new_protected:Npn \property_ref_undefined_warn:
200 {
201   \flag_if_raised:nT { l__property_ref_flag }
202   {
203     \G@refundefinedtrue
204   }
205 }
```

(End of definition for `\property_ref_undefined_warn:`. This function is documented on page 816.)

`\property_ref_undefined_warn:n`

```
\property_ref_undefined_warn:e
206 \cs_new_protected:Npn \property_ref_undefined_warn:n #1 %#1 label
207 {
208   \property_if_recorded:nF {#1}
209   {
210     \G@refundefinedtrue
211     \@latex@warning{Reference~‘#1’~on~page~\thepage\space undefined}%
212   }
213 }
214 \cs_generate_variant:Nn \property_ref_undefined_warn:n {e}
```

(End of definition for `\property_ref_undefined_warn:n`. This function is documented on page 816.)

`\property_ref_undefined_warn:nn`

```
\property_ref_undefined_warn:ee
\RefUndefinedWarn
215 \cs_new_protected:Npn \property_ref_undefined_warn:nn #1#2 %#1 label, #2 property
216 {
217   \property_if_recorded:nTF {#1}
218   {
219     \property_if_recorded:nnF {#1}{#2}
220     {
221       \G@refundefinedtrue
222       \@latex@warning
223       { Property~‘#2’~undefined~for~reference~‘#1’~on~page~\thepage }
224     }
225   }
226   {
227     \G@refundefinedtrue
228     \@latex@warning { Reference~‘#1’~on~page~\thepage\space undefined }%
229   }
230 }
231 \cs_generate_variant:Nn \property_ref_undefined_warn:nn {ee}
232 \cs_set_eq:NN \RefUndefinedWarn \property_ref_undefined_warn:ee
```

(End of definition for `\property_ref_undefined_warn:nn` and `\RefUndefinedWarn`. These functions are documented on page 816.)

## 10.3 Predeclared properties

`abspage`

```
233 \property_new:nnnn { abspage } { shipout }
234 { 0 } { \int_use:N \g_shipout_readonly_int }
```

(End of definition for `abspage`. This variable is documented on page 818.)

**page**

```
235 \property_new:nnnn { page } { shipout } { 0 } { \thepage }
```

(End of definition for `page`. This variable is documented on page 818.)

**pagenum**

```
236 \property_new:nnnn { pagenum } { shipout } { 0 } { \the \value { page } }
```

(End of definition for `pagenum`. This variable is documented on page 818.)

**label**

```
237 \property_new:nnnn { label } { now } { ?? } { \@currentlabel }
```

(End of definition for `label`. This variable is documented on page 818.)

**title**

```
238 \property_new:nnnn { title } { now }  
239 { \exp_not:n { \textbf { ?? } } } { \@currentlabelname }
```

(End of definition for `title`. This variable is documented on page 819.)

**target**

```
240 \property_new:nnnn { target } { now } { } { \@currentHref }
```

(End of definition for `target`. This variable is documented on page 819.)

**pagetarget**

```
241 \newcommand\@currentHpage{}  
242 \property_new:nnnn { pagetarget } { shipout } { } { \@currentHpage }
```

(End of definition for `pagetarget`. This variable is documented on page 819.)

**counter**

```
243 \property_new:nnnn { counter } { now } { } { \@currentcounter }
```

(End of definition for `counter`. This variable is documented on page 819.)

**xpos**

**ypos**

```
244 \property_new:nnnn { xpos } { shipout } { 0 } { \int_use:N \tex_lastxpos:D }  
245 \property_new:nnnn { ypos } { shipout } { 0 } { \int_use:N \tex_lastypos:D }
```

(End of definition for `xpos` and `ypos`. These variables are documented on page 819.)

## 10.4 Messages

```

# ltmiscen.dtx

## 1 Miscellaneous Environments

This section implements the basic environment mechanism, and also a few specific environments including `document`, The math environments and related commands, the ‘flushing’ environments, (`center`, `flushleft`, `flushright`), and `verbatim`.

```
1 <*2ekernel>
2 \message{environments,}
```

### 1.1 Environments

`\begin{foo}` and `\end{foo}` are used to delimit environment `foo`.

`\begin{foo}` starts a group and calls `\foo` if it is defined, otherwise it does nothing.

`\end{foo}` checks to see that it matches the corresponding `\begin` and if so, it calls `\endfoo` and does an `\endgroup`. Otherwise, `\end{foo}` does nothing.

If `\end{foo}` needs to ignore blanks after it, then `\endfoo` should globally set the `@ignore` switch true with `\@ignoretrue` (this will automatically be global).

NOTE: `\@@end` is defined to be the `\end` command of  $\text{\TeX}$ 82.

`\enddocument` is the user’s command for ending the manuscript file.

`\stop` is a panic button — to end  $\text{\TeX}$  in the middle.

*Historical  $\text{\LaTeX}$  2.09 comments (not necessarily accurate any more):*

**\@testdef**

```

196 \def\@testdef #1#2#3{%
197   \def\reserved@a{#3}\expandafter \ifx \csname #1@#2\endcsname
198   \reserved@a \else \@tempswatrue \fi}

```

*(End of definition for \@testdef.)*

Reading data from auxiliary files (like `.toc` normally happens in vertical mode and it therefore doesn't matter if line endings are converted to spaces by  $\text{\TeX}$  during that process.

However, especially the `.toc` file might be read in L-R mode (in cases the `\tableofcontents` attempts to put, say, a list of sub-sections as a paragraph). In that case the newlines after a line like

```
\contentsline {subsubsection}{\numberline {1.1.1}A C-head}{2}
```

might result in spurious spaces (e.g., when that level is not included).

That could be fixed by reading in the file using `\endlinechar=-1` but that has the danger that it drops some valid endlines that should be converted to spaces (for example, when the user edited the TOC and then used `\nofiles` to preserve it).

So the approach taken instead is this:

- `\addcontentsline` adds the command `\protected@file@percent` to the end of the second argument of `\@writefile` that is written to the `.aux`. As the name indicates this is a protected macro so it doesn't change if it is written out.
- When the `.aux` is read back in at the end of the run, `\@writefile` is executed and writes its second argument unmodified to the file with the extension given by its first argument. Or rather that was how it was in the past.
- Instead we change `\@writefile` slightly: basically it looks at the second argument and if the last token in there is `\protected@file@percent` then it is replaced by a percent character and that is then written out. If not (for example, if the data came from a user issued `\addtocontents`, or from some package that uses `\@writefile` for writing its own files) then the command behaves exactly as before.

`\protected@file@percent` Dummy cs to be replaced by a percent sign inside `\@writefile`. If it survives (when used incorrectly) it will expand to nothing in a typsetting context.

```

199 </2ekernel>
200 <*2ekernel|latexrelease>
201 <latexrelease>\IncludeInRelease{2018/12/01}%
202 <latexrelease>          {\protected@file@percent}{Mask line endings}%
203 \protected\def\protected@file@percent{}

```

(End of definition for `\protected@file@percent`.)

`\add@percent@to@temptokena` Helper function which is used to inspect a sequence of tokens (the second argument of `\@writefile` and if the last token is `\protected@file@percent` it will replace it by a harmless percent. The result is saved in `\@temptokena` for later use.

```

204 \catcode'\^^A=9
205 \long\gdef\add@percent@to@temptokena
206   #1\protected@file@percent#2\add@percent@to@temptokena

```

When we call this macro in `\@writefile` we stick in `\@empty` at the beginning, so that in case the tokenlist consists of a single brace group the braces aren't stripped. The `\expandafter` then expands this extra token away again.

```

207   {\expandafter\ifx\expandafter X\detokenize{#2}X\expandafter\dont@add@percent@to@temptokena
208     \expandafter\do@add@percent@to@temptokena\fi{#1}}
209 \long\def\dont@add@percent@to@temptokena#1{%
210   \@temptokena\expandafter{#1}}

```

`latexrelease` will read this code in high-speed mode in certain situations. During that it will only look for `\if` tests but not actually execute the `\catcode` change above. As a result it will drop anything after the `%` character in the definition. Therefore the `\fi` needs to be on the next line and we need locally another comment character to avoid getting spaces into the definition—a weird problem :-)

```

211 \begingroup
212 \catcode'\%=12
213 \catcode'\^^A=14
214 \long\gdef\do@add@percent@to@temptokena#1{\@temptokena\expandafter{#1}\^^A

```

Can't be on the same line as the `%` — see above.

```

215   }}
216 \endgroup

```

(End of definition for `\add@percent@to@temptokena`.)

258     \begingroup\@endpfalse\reserved@a}

```

Before the `\document` code is executed we have to first undo the `\endgroup` as there should be none for this environment to avoid that changes on top-level unnecessarily go to T<sub>E</sub>X's savestack, and we have to initialize all hooks in the hook system. So we need to test for this environment name. But once it has been found all this testing is no longer needed and so we redefine `\@execute@begin@hook` to simply use the hook.

```

259 \def\@execute@begin@hook #1{%
260     \expandafter\ifx\csname #1\endcsname\document
261         \endgroup
262         \gdef\@execute@begin@hook##1{\UseHook{env/##1/begin}}%
263         \expl@@@initialize@all@@
264     \fi

```

If this is an environment before `\begin{document}` we just run the hook so this can be outside the test.

```

265     \UseHook{env/#1/begin}%
266 }

```

Also undo the internal commands as some packages unfortunately test for their existence instead of using `\IfFormatAtLeastTF`.

```

308 <latexrelease>\expandafter\let\csname begin \endcsname\@undefined
309 <latexrelease>
310 <latexrelease>\EndIncludeInRelease
311 <*2ekernel>

```

*(End of definition for \begin.)*

`\end` The top level definition for `\end`.

```

312 </2ekernel>
313 <*2ekernel | latexrelease>
314 <latexrelease>\IncludeInRelease{2019/10/01}%
315 <latexrelease>          {\end}{Making \begin/\end robust}%

```

While `\begin` was made robust simply by using `\DeclareRobustCommand` we need to be a bit more subtle with `\end` as there are packages out there that try to look into the top-level contents of `\end{foo}` (that is at the expansion of `\endfoo`) to see if it contains certain macros. This is done by hitting `\end{foo}` with three `\expandafters`, the first to get

```
\csname endfoo\endcsname          \@checkend{foo}% etc.
```

the second to expand the `\csname`, i.e., to get to

```
\endfoo                          \@checkend{foo}% etc.
```

and the third to finally get to the top-level content of `\endfoo`, i.e.

```
<top-level content of \endfoo> \@checkend{foo}% etc.
```

Therefore a robust replacement should produce the same results after three expansions (there first is obviously different).

Basically the definition of `\end` should either produce `\protect\end_` (when not doing typesetting) or it should produce `\end_` (without the `\protect`) when doing typesetting. Furthermore, it should (when in typesetting mode) show exactly the same result as `\end_` (which is the original fragile definition of `\end`) when you expand either of them twice, i.e.,

```
\endfoo                          \@checkend{foo}% etc.
```

That is achieved with the code below (which is worth studying carefully).

There is some trickery involved here: in particular we use `\romannumeral` to change a single expansion into three successive expansions in one go. That primitive expands until it has scanned a number (0 in this case, so it doesn't produce any output) and so it allows us to place arbitrary many `\expandafters` inside that are all going to be executed when `\romannumeral` is hit by a single `\expandafter`.

```

316 \edef\end
317   {\unexpanded{%
318     \romannumeral
319     \ifx\protect\@typeset@protect
320       \expandafter      %1
321       \expandafter      %2
322       \expandafter      %1
323       \expandafter      %3 expands the \csname inside \end<space>
324       \expandafter      %1
325       \expandafter      %2 expands \end<space>
326       \expandafter      %1 expands the \else
327       \z@
328     \else
329       \expandafter\z@\expandafter\protect
330     \fi
331   }%
332   \expandafter\noexpand\csname end \endcsname
333 }
334 </2ekernel | latexrelease>
335 <latexrelease>\EndIncludeInRelease

```

And here is the original definition of `\end` the way it was in L<sup>A</sup>T<sub>E</sub>X for several decades now hidden in `\end_`.

```

336 <latexrelease>\IncludeInRelease{0000/00/00}%
337 <latexrelease>          {\end}{Making \begin/\end robust}%
338 <latexrelease>\def\end#1{%
339 <latexrelease>  \csname end#1\endcsname\@checkend{#1}%
340 <latexrelease>  \expandafter\endgroup\if@endpe\@doendpe\fi
341 <latexrelease>  \if@ignore\@ignorefalse\ignorespaces\fi}
342 <latexrelease>
343 <latexrelease>\EndIncludeInRelease
344 <*2ekernel>

```

(End of definition for `\end`.)

`\end\verbvisiblespace` The internal version with a space at the end.

```

345 </2ekernel>
346 <*2ekernel | latexrelease>
347 <latexrelease>\IncludeInRelease{2024/11/01}%
348 <latexrelease>          {\end!space}{New @endpe handling}%
349 \@namedef{end }#1{%
350   \romannumeral

## 1.2 Center, Flushright, Flushleft

```

414 \message{center,}

```

Historical *LaTeX* 2.09 comments (not necessarily accurate any more):

```

\center, \flushright and \flushleft set
  \rightskip = 0pt or \@flushglue (as appropriate)
  \leftskip  = 0pt or \@flushglue (as appropriate)
  \parindent = 0pt
  \parfillskip = 0pt. (except \flushleft)
  \\\          == \par \vskip -\parskip
  \|[LENGTH] == \\\ \vskip LENGTH
  \\\*         == \par \penalty 10000 \vskip -\parskip
  \\\*[LEN]    == \\\* \vskip LENGTH

```

They invoke the `trivlist` environment to handle vertical spacing before and after them.

`\centering`, `\raggedright` and `\raggedleft` are the declaration analogs of the above.

`\raggedright` has a more universal effect, however. It sets `\@rightskip := flushglue`. Every environment, like the list environments, that set `\rightskip` to its 'normal' value set it to `\@rightskip`

End of historical *LaTeX* 2.09 comments.

### 1.3 Verbatim

```
500 \message{verbatim,}
```

The verbatim environment uses the fixed-width `\ttfamily` font, turns blanks into spaces, starts a new line for each carriage return (or sequence of consecutive carriage returns), and interprets *every* character literally. I.e., all special characters `\`, `{`, `$`, etc. are `\catcode`d to 'other'.

The command `\verb` produces in-line verbatim text, where the argument is delimited by any pair of characters. E.g., `\verb #...#` takes '...' as its argument, and sets it verbatim in `\ttfamily` font.

The \*-variants of these commands are the same, except that spaces print as the T<sub>E</sub>Xbook's space character instead of as blank spaces.

`\@vobeyspaces`  
`\@vobeytabs`

518 <latexrelease>\EndIncludeInRelease
519 <*2ekernel>
```

(End of definition for \@vobeyspaces and \@vobeytabs.)

`\@xobeysp`

(End of definition for \@xobeysp.)

`\@xverbatim`  
`\@sxverbatim`

```
520 \begingroup \catcode '|=0 \catcode '[= 1
521 \catcode']=2 \catcode '\{=12 \catcode '\}=12
522 \catcode'\=12 |gdef|@xverbatim#1\end{verbatim}][#1|end[verbatim]]
523 |gdef|@sxverbatim#1\end{verbatim*}][#1|end[verbatim*]]
524 |endgroup
```

(End of definition for \@xverbatim and \@sxverbatim.)

`\@verbatim` Real start of verbatim environment We use `\relax` to prevent `\item` scanning too far.

```

525 </2kernel>
526 <*2kernel | latexrelease>
527 <latexrelease>\IncludeInRelease{2017-04-15}{\@verbatim}%
528 <latexrelease>          {Disable hyphenation in verbatim}%
529 \def\@verbatim{\trivlist \item\relax
530   \if@minipage\else\vskip\parskip\fi
531   \leftskip\@totalleftmargin\rightskip\z@skip
532   \parindent\z@\parfillskip\@flushglue\parskip\z@skip

```

Added `\@@par` to clear possible `\parshape` definition from a surrounding list (the verbatim guru says). Switch language when in vertical mode.

```

533   \@@par

```

Set `\language` here to suppress hyphenation. Done this way rather than setting `\hyphenchar` as that is a global setting.

```

534   \language\l@nohyphenation
535   \@tempswafalse
536   \def\par{%
537     \if@tempswa

```

A `\leavevmode` added: needed if, for example, a blank verbatim line is the first thing in a list item (wow!).

```

538       \leavevmode \null \@@par\penalty\interlinepenalty
539     \else
540       \@tempswatrue
541     \ifhmode\@@par\penalty\interlinepenalty\fi
542   \fi}%

```

To allow customization we hide the font used in a separate macro.

```

543   \let\do\@makeother \dospecials
